THE LANCET.

urnal of British and Foreign Medicine, Surgery, Obstetrics, Physiology,
Chemistry, Pharmacology, Public Health, and News.

IN TWO VOLUMES ANNUALLY.

VOL. I. FOR 1913.

NINETY-FIRST YEAR.

SAMUEL SQUIRE SPRIGGE, M.A., M.D. CANTAB.,
EDITOR:

LONDON:
AND PUBLISHED BY THE REGISTERED PROPRIETORS, AT THE OFFICES OF "THE LANCET," No. 423, STRAND
AND Nos. 1 & 2, BEDFORD STREET, STRAND.

Air, chemical state of, 1285; compressed, accidents owing to, 1612; expired, supposed existence of organic poisons in, 1286; Fresh, Plans for Obtaining, in Modern Houses (Dr. T. S. Carrington) (review), 253; hot, treatment of bedsores by, 1684

Air embolism, fatal, due to attempts to induce abortion, 706

Air-passages, Diseases of, 1912 (Drs. A. Denker and W. Brunings) (review), 1806

Albert Medal, award of, to Miss E. Holley, 496

Albuminuria associated with chronic nephritis, 1364; chronic, with hepatic enlargement, case of, 635; in pregnancy, some points in determining signification of (Dr. H. Williamson), 1363; questiin of recurrence of, in successive pregnancies, 1683

Alcock, Dr. N. H., obituary, 1835

Alcohol, absence of, in inoperable cancer, 216; application of, in treatment of burns, 705; effect of, 129, 197; and drunkenness, 61; injection of, in neuralgia, hyoscine-morphia anæsthesia for (Dr. W. Harris), 881

Alcoholism, Clinical Aspects and Treatment of (Dr. F. Hare) (review), 104

Alexander, Dr. W., necessity of a better classification of epileptics, 263

Alford, Dr. H. J., medical officer of health of Taunton for 40 years, 489

Algiers, Winter in (From Cloud to Sunshine), 1912 (Dr. A. S. Gubb) (review), 838

Alimentary toxæmia (see Toxæmia, alimentary)

Alkaloid, spectrum of, as aid to detection and estimation of, 1399

Alkaptonuria, specimens from case of, 35

All India Sanitary Conference, 473, 486

Allan, Dr. C. J., memorial to, 575, 631

Allchin, Sir W., memorial to, 575

Allen, Mr. C. H., spinal anæsthesia, 1100

Allen, Dr. R. W., Bacterial Diseases of Respiration and Vaccines in their Treatment, 1913 (review), 1593; Vaccine Therapy: its Theory and Practice, 1912 (review), 1320; vaccine treatment in pneumonia, 116

Allison, Dr. A., and Glaister, Dr. J., culinary and chemical experiments with aluminium cooking vessels, 843

Aluminium, some kitchen experiments with, 54

Amand, Rev. Dr., obituary, 1838

Amœbiasis, treatment by emetine, 1132

Amblard, M., and Morel, M., delayed death from local asphyxia, 134

Ambulance, Dutch, at Balkan war, 706; Indian, in Turkey, 858; (see also Field ambulance; Regimental ambulance)

Ambulance work, instruction of police in (United Provinces, India), 1838

Ambulances, need for, in County of London, 293; supply of, for London (leading article), 700

America, abuse of hypnotic drugs in, 768; relapsing fever of, transmission of, 86

American Otological Society, Transactions, vol. xii., part iii. (review), 837

American Society of Medical Economics, establishment of, 493

Ammonia (ichthyol), 328

Amphotropin, 1324

Amyloid disease, case of, 1533

Anæmia, secondary, with secondary hæmorrhages in retina, 611; slight splenomegaly, and nervous disorder in case of chronic alcholuric jaundice, 171; splenic, case of, 389; splenectomy for, after-history of two cases, 1388

Anæmia and bone-marrow metastases, in gastric ulcer (Dr. A. W. Harrington and Dr. A. M. Kennedy), 378

Anæmic infarcts of small intestine, case of, 911

Anæsthesia, with ethyl chloride, 1630; general, technique in, for intranasal operations, 825; inhalation, scopolamine-morphine-atropine as adjunct in, 825; intravenous, 38; Local, Surgical Operations with (Dr. A. E. Hertzler) (review), 1321; local and spinal, 1100; opinion of surgeons upon, use of nitrous oxide and oxygen, 333; question of use of in operation for exophthalmic goitre, 671; treatment of post-anæsthetic troubles, 67

Anæsthetics, dieting of patients immediately before administration of, for surgical operations, 1611; fees for, under National Insurance Act, 795; administration of, by unqualified persons (Parliamentary question), 1357; general, scopolamine-morphine-atropine as, 825; and surgeon dentists, 279

Anæsthetist, relations of operator to, 719

Analyst of Birmingham, report of, 1421

ANALYTICAL RECORDS FROM THE LANCET LABORATORY.—Ammonium ichthyol, 328—Ampoules pituitary liquid, 903—Aphrodont, 44—Azodolen, 44—Azodermin, 545—Bronamalt, 1675—Bynolecithin, 328—Dried bananas, 44—"Elyos" standard bread, 545—"Emile" rectal suppositories, 1325—Empire stout, 1675—Fructolax, 328—(1) Hediosit, and (2) Amphotropin, 1324—Hypotubes, 903—Irocose, 329—Kinazyme, 44—Kitchen experiments with aluminium, 54—La Presto natural mineral water, 545—Magnesia compound, 545—Neu-Selters table water, 44—Olive oil, 1674—Pellidol, 44—Perogen bath, 1325—Phosphocose, 903—"Phylacogens," 1674—Propacsin, 1674—Secretogen, 44—Soluble salts of acetyl salicylic acid, 1325—Supreme olive oil, 545—Tabloid emetine hydrochloride keratin coated, 43—(1) "Tabloid" hypodermic morphine hypophosphite, (2) "Tabloid" digitalin crystalline, 329—Thyroid gland, new tabloids of, 43—Tuberculin bouillon filtrate, 43—Various cyders, 329—Vesalvine S., 903—Wine vinegar, 903

Anapyhylaxis, some studies in, 461

Anastomosis, facio-hypoglossal, case of (Mr. E. C. Bevers), 1450

Anatomical nomenclature, present crisis in, 691

Anatomical and Pathological Institute, suggested, 510

Anatomy, Dental, 1913 (Mr. A. Hopewell-Smith) (review), 1534

Anatomy, Practical, Cunningham's Manual of, vol. ii., Thorax, Head, and Neck (the late Prof. D. J. Cunningham) (review), 618; Gross Anatomy from Topographical Standpoint, Dissection of Human Body (Dr. J. C. Heisler) (review), 248; skit on (Astonishing Anatomy) (review), 1030; and Physiology for Nurses, 1912 (Dr. E. R. Bundy) (review), 900

Ancients, the, Surgical Instruments of (Prof. T. Meyer-Steineg) (review), 468

Andaman Islands, Malaria in, 1912 (Maj. S. R. Christophers) (review), 836

Anderson, Mr. C. V., and Corner, Mr. E. M., case of recovery after severe electric burns, 1096

Anderson, Mr. W., and Gray, Mr. H. M. W., remarks on abnormal intra-abdominal developmental adhesions, 1300, 1373

Andouard, M., impure salt, 1057

Andrew, Mr. J. G., operation for acute appendicitis, primary closure of the abdominal wound, 832

Andrewes, Dr. F. W., discussion on alimentary toxæmia, 754

Andrews, Mr. C. B., An Introduction to the Study of Adolescent Education, 1912 (review), 834

Andrews, Dr. H. Russell, unusual case of rupture of the uterus, 1454

Aneurysm, cirsoid, case of, 100; intrathoracic (Dr. F. de H. Hall), 803, 869, 945; diagnosis, 872; by X rays, 870; medical treatment in, 945; modes of termination, 871; pupils in, 869; surgical treatment in, 949; of Robert Liston, 1625—tracheal tugging in, 869; tracheotomy in treatment of, 948; of abdominal aorta, 321; of descending thoracic aorta, case presenting some unusual features, 683; of superficial palmar arch, 1038; of thorax, two cases, 322; traumatic, case of, 1733; tuberculous, of common iliac artery, 1816

Angina (see also Tobacco angina)

Angio-sclerosis, 1317

Anglo-Saxons, colonisation of, in tropics, difficulties of, 917

Angus, Mr. H. B., and Hall, Dr. G., case of subcortical cerebral tumour, tuberculous in nature, removed by operation, recovery, 678

Animal Kingdom, Growth of Groups in (Dr. R. E. Lloyd) (review), 1321; organisms, protective ferments of, 128

Animals, diseases communicable from, to man, 1388; goitre in, 150; "humane slaughter" of, demonstration in Salford, 1769; intracellular parasites in syphilis and in allied conditions in, 1025; transmission of aphthous fever from, to man, 1494; transmission of goitre to, from man, experiments dealing with, 370

Ankylosis, "pseudo-Babinski" sign in, 1126

Ankylostomiasis, case of, in Birmingham (Prof. R. Saundby), 1223

Annals of Tropical Medicine and Parasitology (review), 42, 476, 1325

Annam, vaccination in, 67

Anodynes, use of, in inoperable cancer, 216

Anomalies, congenital, connected with umbilical structures, 245

Another Device (Mr. S. Paget) (review), 541

Antarctic expedition of Captain Scott, tragedy of, 472

Anthrax, death from, at Warrington, 1136; vaccination against, 1057; in wool trade, 766

Anti-alcohol Association, annual meeting in Berlin, 1351

Antiseptics, intestinal, in treatment of goitre, 368

Antithrombin and thrombin, action of, 688

Antituberculosis Institute, establishment of, at Rochelle, 651

Antityphoid Committee, report of, 1476

Antivaccinationists, short way with, 1332

Antrum, soft bony growth of, case of, 243; suppuration of, due to aspergillus fumigatus, case of, 613

"Anxiety Neurosis" and its Treatment (Nervose Angstzustände unde ihre Behandlung) (Dr. W. Stekel) (review), 617

Aorta, abdominal, aneurysm of, 321; descending thoracic, aneurysm of, case presenting some unusual features, 683

Aorta, syphilitic diseases of, 1496

Aphonia, functional, method of curative and preventative treatment (Mr. C. MacMahon), 632

Aphrodont, 44

Aphthous fever, transmission of, from animals to man, 1494

Apparatus, three forms of, for treating injuries of hands, 617

Appendicitis, acute, operation for, primary closure of abdominal wound, 832; as local manifestation of general infection, 119; chronic, Bastedo's sign a new symptom of (Dr. A. F. Hertz), 816; coxalgia in, 1112; immediate operations in, discussion on, 528; in children, 1024; plea for immediate operation, 717; (Mr. E. Owen), 441; question of time for operation in, 640, 782, 851, 985, 1266, 1342, 1762; statistics for operation for, 641; (leading article), 548; time for diagnosis in, 1825; traumatic, 1180

Appendix, vermiform, peculiar, specimen of, 390; adherence of, to Fallopian tube, case of, 690

Appointments, weekly lists of, 75, 142, 210, 292, 359, 429, 501, 577, 657, 730, 797, 864, 931, 1002, 1068, 1141, 1211, 1280, 1357, 1429, 1501, 1569, 1637, 1709, 1843

Appointments, 1781; whole-time, priority for (Parliamentary question), 209; whole-time, under Insurance Act (Parliamentary question), 141

Approved societies and medical men (Parliamentary question), 1139

Arany, Dr. S. A., the individual treatment of diabetes, 884

Arber, Mrs. A., Herbals, their Origin and Evolution (review), 49

Arbroath, new infirmary at, 133

Arc light, exposure to, followed by unilateral optic atrophy, 887

Archiv für Schiffs- und Tropen-Hygiene (review), 275, 715, 1691

Archives de Médecine et Pharmacie Navales, 127, 342, 1192, 1341

Argentina, bacteriology in, 207

Argentine Medical Society, 1633

Argyllshire, Insurance Act in (Parliamentary question), 290

Argyria of bladder associated with cystitis and prolonged use of catheter, 794

Aristotle as a Biologist (Herbert Spencer Lecture, Professor D'A. W. Thompson) (review), 836; Works of, De Motu Animalium, De Incessu Animalium (Mr. A. S. L. Farquharson) (review), 620; Works of, edited by Mr. W. D. Ross, 1913 (review), 1806

Armlet, improved, for sphygmomanometers, 468

Armour, Mr. D. J., case of unusual injury to ulnar nerve, 1098

Armour, Mr. T. R. W., two cases of recurring dislocation of the shoulder treated by "Clermont's" operation, 688

Arms, splints for, 1246

Armstrong, Dr. E. F., The Simple Carbohydrates and the Glucosides, 1912 (review), 622

Armstrong, Mr. H. G., and Fortescue-Brickdale, Dr. J. M., Manual of Infectious Diseases Occurring in Schools, 1912 (review), 970

Armstrong, Mr. W., discussion on alimentary toxæmia, 1384; discussion on treatment of arterio-sclerosis and high tension, 1314

Armstrong, Dr. W. E. M., case of gonorrhœal warts on the face successfully treated by vaccine, 1382

Army, Austrian, training of surgical nurses for, 1424; Austro- [illegible] ment of, in readi [illegible] health of, in 19 [illegible] regal Lodge Fund for, 1058; and Army Medical Corps, British, health of (Parliamentary question), 930

Army and Navy, Male Nurses' Coöperation, 732

Army Medical Advisory Board, 128

Aronson, Mr. H., Our Village Homes, Present Conditions and Suggested Remedies, 1913 (review), 1462

Arris and Gale lectures on the genital functions of the ductless glands in the female, delivered at the Royal College of Surgeons of England (Dr. W. B. Bell), 809, 937, 986

Arrowsmith, Mr. J. W., obituary, 348

Arsenic, administration of, therapeutically, pneumonia during, 319

Arsenical poisoning due to paint, outbreak of, 1610

ia salina recovered from nose, 613

The Purvis Lecture

ON

THE TREATMENT OF INOPERABLE CANCER.

Delivered before the West Kent Medico-Chirurgical Society on Dec. 6th, 1912,

BY SIR ALFRED PEARCE GOULD, K.C.V.O., M.S. LOND., F.R.C.S. ENG.,

SENIOR SURGEON TO THE MIDDLESEX HOSPITAL.

MR. PRESIDENT AND GENTLEMEN,—My first word must be one of grateful acknowledgment of the compliment paid to me in asking me to visit you and to deliver this address—a compliment that is enhanced by the distinction of those who have preceded me in this office and by the presence in the chair to-night of my old and valued friend Mr. Willmott Evans. He it was that suggested that I should select as my subject to-night "The Treatment of Inoperable Cancer," and as I have been for 30 years on the surgical staff of the Middlesex Hospital, and for more than half of that time have had charge of patients in the Cancer Charity of the hospital, I felt that I could do no other than adopt Mr. Evans's suggestion.

GENERAL TREATMENT OF CASES OF INOPERABLE CANCER.

My subject naturally divides itself into two parts, the general treatment of cases of inoperable cancer, and the special treatment of cancer other than by operation for its removal. I will deal with it in this order.

Importance of Mental and Physical Rest.

We sometimes hear it said that "the doctors have given up So-and-so and can do nothing for him," and I want at the outset to enter my protest against the view that, because no operation is possible and no specific treatment is being tried, our art is helpless. One of the first things I learned when I had charge of some of these advanced cases of cancer in the Cancer Charity of Middlesex Hospital was that, with scarcely an exception, every one of them improved after coming into the ward—many of them improved quite markedly—and that the duration of life was nearly always much more than I had anticipated. In other words, the hospital treatment is of great value to them. Part of this good is, I think, the result of mental rest; the relief of anxiety when a very poor man or woman is removed from a poverty-stricken home into a well-appointed hospital, with the assurance that the stay there is to be as long as life lasts, is very great.

The mental quietude the patients usually exhibit is quite striking, and I believe it has important physical effects. In its absence we usually find ourselves unable to relieve these patients as we are accustomed to do. I have often heard from the sister of the ward that "No. so-and-so has not settled down yet," and this is given as the explanation of physical ills. This "settling down" is an important condition of physical well-being in these poor sufferers; it means more than getting accustomed to new and strange surroundings, to the getting over the separation from "home"—a word that is as sacred and as full of meaning upon the lips of a poor hospital patient as from anyone. It means the absence of anxiety about husband or wife and children, the confidence that one's own wants will be met even to the end, and I have come to think that the knowledge of the incurable nature of their illness is also, as a rule, not without its helpful influence. Here, I know, I am making a statement that will not win general acceptance. I am very often requested by the friends of patients not to let them know that they are suffering from cancer, and such a request one is bound to respect. But all the same, I must say that in my experience the knowledge of the real state of affairs has very rarely seemed to do harm, and in the late stage of the disease, when curative measures are not to be thought of, and palliation is our function, it has seemed to do great good.

Only the other day on visiting my cancer patients I came to one who had been in the ward about a month, and was the subject of a very extensive ulcerated cancerous growth in the chest wall—a recurrence after excision of the mamma. I remarked to her on her improvement since she had come in, and asked her how it was. Her answer was that she had everything done for her, and that she had "*no worry*." I have often asked one of the sisters of the Cancer Charity her opinion on this point. She is a woman who possesses the qualifications for her particular work more fully—indeed, I may say more perfectly—than I have ever known them combined in any other individual. I have, therefore, great confidence in quoting her opinion. She has no doubt at all that it is wise to let such patients as come under her—cases of late cancer—know the grave nature of their disease, and that recovery is not to be expected. As an example, she reminded me of a poor woman with advanced uterine cancer, who used to greet her every morning with a tale of the wakefulness of the previous night, of the pain she was then suffering, and of her other troubles. This went on day after day in spite of efforts to relieve her, till one day the sister had an opportunity of having a quiet chat with her, and told her that she feared she was not going to get well. At once the picture changed, she became quiet, uncomplaining, and apparently in far greater comfort, and she told the night nurse when she came on duty what the sister had said to her and how glad she was to know it.

This is a quite usual experience, and in view of it I cannot share the common opinion that patients with malignant disease are to have this fact most carefully concealed from them. Indeed, were it so, the Middlesex Hospital Cancer Charity would be a cruel mistake, its very name would condemn it, and to have wards full of patients, each of whom passes out through the portal of death, would be only to add to the calamities of those it seeks to succour. A visit to these wards soon removes such an illusion; they are, of course, pathetic to those in enjoyment of full health, but the comfort they bring to the patients, and even the brightness they often add to the closing months and weeks of life, are beyond all cavil or question. Of course, I need not explain that I am not advocating either premature or callous or careless lifting of the veil. It requires judgment when to do it, it always needs wise tact in the doing.

One often has occasion to observe the bad effects of mental worry in these patients. Time and again when I find a patient not so well, with more pain or weaker, I learn that there has been some home worry that has caused it—a husband or child ill, or not behaving well, or children uncared for, or the little home broken up, or the sudden cessation of accustomed correspondence. The influence of mind on matter is seen with quite special force and clearness in cases of advanced cancer.

Along with mental rest I attach great importance to physical rest. The degree of this must vary with the powers of the patient and the stage and situation of the disease, but the general working rule I have is to urge my patients never to take any physical exercise or do any work that causes any sense of fatigue. So long as walking exercise is only a pleasure, it should be enjoyed. Later on, it is of service to these patients to sit in the open air and bask in the sunshine when that can be secured. So soon as leaving their bed is any effort or fatigue to them, I always press them to stay in bed. So far as I have observed these patients, rest is one of the primary conditions of their well-being.

The Observance of Strict Cleanliness.

Second only to rest in the management of these cases is cleanliness. In cancer of the mouth, great good follows the frequent use of a mouth-wash, or the gentle removal of particles of food, mucus, or discharge with pledgets of cotton wool. Pyorrhœa should be dealt with with all the rigour of the dentist's art. We must never think that because a patient has hopeless disease it is not worth while to attend to these details, even at the cost of much trouble. I have so often seen great benefit result from these measures that I have no hesitation in urging their adoption. The mouth-wash I prefer is sanitas and water in the proportion of 1 to 2 drachms in 5 ounces, but it is the frequency and thoroughness with which the lotion is used that are of more consequence than the composition of the lotion, provided only that it is not irritating. The mouth must, of course, be well cleansed before and after taking food and at more frequent intervals according to circumstances. I may here add that all loose teeth should be extracted, and that the removal of sloughs and sequestra is often followed by considerable relief.

In uterine cancer the frequent careful use of non-irritating antiseptic douches is, of course, indicated. When hæmorrhage occurs the douche should be as hot as the patient can bear. Here, too, the removal of sloughing masses or the careful curetting of fungating growth is attended with benefit; the curette must be used with care, remembering that in extensive disease it may readily penetrate peritoneum, bladder, ureter, or rectum.

For cancer of the rectum similar measures add much to the patient's comfort; the gentle removal of all particles of fæcal matter or discharge should be attended to. Where colotomy has been done, the washing through of the bowel from artificial to natural anus should be regularly carried out whenever it is possible—I have often been surprised at the amount of local relief and general improvement that have followed this measure. For this purpose I have found nothing better than sanitas and water, an ounce to the pint.

The same care should be taken to keep external cancer as clean as possible. This may be effected by the use of antiseptic lotions, ointments, and dressings; in other cases the use of X rays will be found very beneficial in "cleaning up" extensive and foul cancerous ulcers, and the diathermic cautery will effect the bloodless removal of sloughing or fungating growths, to the very great advantage of the patients.

In addition to such local cleanliness, the general cleanliness of the body and of the patients' habits of course adds to their comfort, and I think also helps them to fight the disease. I have thought that this was one of the smaller ways in which we help the poorest and most neglected among those who come into our Cancer Charity.

The Nature of the Diet.

As to diet, I need say but very little. It should be simple, easily digestible, and varied. I know of no necessity to exclude meat, or fruits, or vegetables. It should not be excessive; in the latest stages these patients are often able to take only very little food, and to give them more only causes vomiting or adds to their pain. In cancer of the mouth or pharynx it is very important that the food should be unirritating and should not require masticating; within these limits, however, it should be as varied as possible, and should include fruit, vegetables, and farinaceous food, as well as milk. I find it very important to warn my poorer patients not to spend their money upon costly beef-tea and meat extracts of little or no nutritive value. There is still a very widespread belief that these preparations are necessary constituents of the diet of all invalids; they may, of course, be taken, but they are not essential, and should never be used instead of the more nutritive milk and eggs. As to other fluids, cocoa is very useful, tea taken neither very hot nor very strong is good, coffee is not so advisable.

Abstinence from Alcohol.—Use of Sedatives and Anodynes.

Alcoholic stimulants of all kinds are, as a rule, to be avoided. I am sure that patients with cancer are better without them; anything approaching a free use of alcohol adds greatly to the activity of the disease. All of us must have been impressed with the malignity of cancer in the intemperate. Patients in our Cancer Charity are allowed to go home occasionally, either for special business or family reasons or for a "holiday," as it is called. They usually come back the worse for the change, and we are generally able to trace this to indiscreet indulgence in alcohol. To mention a concrete case: there is a man under my care now with an extensive epithelioma of the mandible. Last summer he was granted permission to go home for a few days to attend to urgent business matters. He came back to us quite a different man, looking haggard, suffering much pain, and the growth was more active and ulcerative. This was all the result of a free indulgence in alcohol; he is now in a very different state, but he has never got quite back to the condition he was in before that ill-starred "holiday."

I have seen much ill follow the use of alcohol in cancer, and I never order it for this disease. But I very occasionally allow it to be taken. A patient with extreme distaste for food can sometimes be induced to take food if allowed to sip a little beer or wine; in such a case the beer must never be given instead of food, but only as an adjunct to food. Again, some patients have a great craving for stimulants when feeling very weak, and they beg to be allowed to take some; [illegible] re so accustomed to take beer or wine with their food [illegible] protest they cannot eat without it. I find that most of these patients only want a little management, and to understand that in no case will the alcohol benefit their disease, to consent to go without it; but some will not without an undue restriction upon their liberty and happiness.

We all know the force of an appeal coming from one suffering from an incurable malady, whose days here are numbered; unless it is wholly unreasonable we have sometimes to yield. But I wish to make my position in this matter quite clear: I do not regard alcohol as helpful in the treatment of cancer, I believe it to be prejudicial and to make the disease more active and more distressing. I should never order it, and I should only consent to its being taken under special circumstances, and then only in small quantity.

As to sedatives and anodynes, they undoubtedly have a place in the treatment of this disease. Opium and its derivatives I use as sparingly as I can. I have seen cases where the ill-effects of morphia have been more distressing than those of the cancer for which it was prescribed. The patients in our Cancer Charity have little morphia; it is a common event for not a single hypodermic injection of morphia to be given to any one of our 90 patients. Aspirin is given to many of the patients, phenacetin to others; many have a dose of nepenthe at night. Opiates are generally given in the form of the solution of morphia, or of nepenthe by the mouth, or of small suppositories of morphia; only occasionally is a hypodermic injection of morphia used, and we aim at keeping down to a minimum our use of this drug.

When I first saw the practice in our cancer wards—more than 30 years ago—the custom was to prescribe both alcohol and morphia freely; now both are used sparingly, if at all. The difference in the wards is quite remarkable; the patients then suffered far more, and were more irritable, fractious, and difficult to deal with. Now we have no disciplinary trouble, and the patients are far happier and more comfortable. Had I not seen the two systems tried, and myself witnessed the difference in results, I could hardly have credited the value of our present practice as contrasted with that of our predecessors.

Regulation of the Bowels.

Under this division of my subject, there is only one other detail I must refer you to, and that is attention to the regular action of the bowels. It is most important for the comfort of these patients that the bowels should act regularly every day, or at most, every other day. Constipation adds most markedly to their distress; in no case is this more marked than in uterine cancer. I need not here discuss the relative value of the various aperients; I will only say that purging is to be carefully avoided, and the value and harmlessness of a carefully given enema not forgotten.

To sum up, then, the general treatment of late cancer, I should say it should consist in the avoidance of all fatigue, strain, and worry, the observance of strict cleanliness, care and moderation in diet, the proper regulation of the bowels, abstinence from stimulants, and the minimal use of opium and its derivatives consistent with the reasonable comfort of the patient.

PALLIATIVE OPERATIVE MEASURES.

There are certain palliative operations for incurable cancer that may be practised with considerable advantage in properly selected cases. They have received a good deal of attention from surgeons and I need not deal with them at great length.

Gastrostomy.

In my experience gastrostomy is a most valuable procedure in cases of malignant stenosis of the gullet. I prefer Senn's operation, in which the inversion of the stomach wall is used to make a valvular opening into the stomach. I recommend this operation as soon as patients can swallow only fluids; the operation is attended then with very little shock or other danger, food is introduced into the stomach from the first, and the patient very quickly improves in comfort and strength. He is able to feed himself without difficulty or leakage, and not infrequently resumes his work. He may recover some of his lost power of swallowing, life is prolonged for months, sometimes for years, and the patients are spared the pains of death from starvation.

There is in the Cancer Charity at the present time a man who was transferred in January, 1912, from one of the homes for the dying (Friedenheim), with advanced epithelioma of the gullet 15 inches from the teeth, he could swallow thin fluids only and was greatly emaciated and weak I performed gastrostomy for him, and he is now well nourished even plump free from all discomfort, and he has so far recovered his power of swallowing that he takes finely minced meat and vegetables bread and butter, and milk puddings per os He uses the tube into his stomach at least once a day The œsophagoscope shows the annular growth very little, if at all, altered He is up and about all day *and is quite fit for light work, under the terms of the* Charity he is, however eligible for residence with us, as the *disease is still present*

It is important to feed these patients on a mixed diet and where a large tube is used this offers no difficulty, I employ a rubber catheter, No 18 English scale Through that, not only milk and egg, but finely pounded meat vegetables fruit, and bread stuffs can be given If the food when prepared is passed through a sieve of proper mesh there is no fear of blocking of the tube Gastrostomy has I know, been condemned, but I am convinced that it is a good operation, it gives great comfort and no little prolongation of life it does not incapacitate the patient, and is unattended with annoyance

Colostomy

Colostomy for irremovable cancer of the colon or rectum is still the subject of discussion and difference of opinion I am in favour of the operation when there is marked obstruction, severe pain connected with the passage of motion over the ulcerated surface or free hæmorrhage from the growth In these circumstances it prolongs life, saves the patient from the distress attending complete obstruction, and lessens pain In the best cases there is very little trouble connected with the artificial anus, and the patient can follow his employment and is in no way cut off from society All cases are not "the best" however, and we sometimes have a good deal of trouble with the artificial anus difficulty in securing the proper evacuation of the bowel, much discharge and not great relief of pain

I do not advise the operation as a routine measure in all cases of irremovable cancer of the rectum, many of these cases can be helped through their difficulties to the end without the operation It should be employed only when there is definite indication for it, but I have seen such very great relief and benefit follow this operation that I cannot but advise patients to consent to it, and I could not join in the general condemnation of the operation that we sometimes hear I have already referred to the need for regular *and careful cleansing of the bowel below the colostomy,* other details I must not stay to refer to now

Cystostomy for Cancer of the Bladder or Prostate

This operation is sometimes of value I have a very clear recollection of one case, however, in which apparently it afforded no relief to the patient's sufferings, on the other hand I recall several patients who expressed themselves very grateful for the ease it gave them It is especially indicated where the growth bleeds and clots are passed with *great difficulty and pain, and where micturition is very* frequent and agonising

The application of an electric cautery to the neck of the bladder is another means of affording considerable relief to cases of cancer of the prostate where the growth is blocking the urethra and the use of a soft catheter is either attended with great pain or is impossible

Gastro enterostomy—Neurectomy

Gastro-enterostom
is generally attende
longation of life I

Neurectomy for
selected cases certainly has a place in surgery The last case in which I employed it was that of a woman under my care in Queen Mary Ward last June, she had had her right breast amputated for cancer in January, 1911, and when she came under my care she had an extensive recurrence in the neck of the same side which by pressure upon the nerves of the brachial plexus caused *very severe* and continuous pain in the whole of the upper limb She had no sign of deeper recurrence In that case I performed cervical laminectomy and divided the posterior roots of the nerves from the third cervical to the second dorsal inclusive on the right side She lost her pain entirely and expressed herself as very grateful for the relief, which continued up to the time of her death in July

Paracentesis

Paracentesis either of the pleura or peritoneum is a simple *operative procedure often attended with great benefit* As a rule the fluid re collects and sometimes very rapidly, but this is not always the case I should postpone tapping until the pressure of the fluid is causing *marked dyspnœa* or abdominal distress but at that point the relief afforded is very welcome to the patients

As an example of the value of this procedure and of the remarkable results occasionally obtained I may mention a case I saw in consultation with Dr W H Bourke The patient was a married lady aged 43 whom I saw first in June, 1909 She was sitting up in bed suffering from extreme dyspnœa, the right chest was dull all over and entirely immobile, the heart's apex beat was felt in the left axilla She was very emaciated and the right mamma was the seat of a small atrophic scirrhus for which she had never sought advice I punctured the right pleura and drew off a wash basin full of serous fluid, the relief afforded was immediate and very great In a month I was called in again as the dyspnœa had recurred and I then drew off nearly the same quantity of fluid from the right pleura I had to tap the right pleura again on Sept. 28th and in December On Jan 20th, 1910, I was summoned in a great hurry and found the lady in really very urgent distress, the dyspnœa was even more alarming than before and I now found signs of fluid in both pleuræ From the right pleura *I drew off about two pints and from the left pleura three* pints She was again at once completely relieved *From this date no further collection of fluid occurred in either pleura*, the right side of her chest gradually contracted down and eventually became quite dull and immobile, and no breath sound was audible in it—the result of cancerous growth The left lung and pleura were unaffected Soon after the fifth and last tapping of the pleura we found that fluid was accumulating in the peritoneum, this was drawn off with Southey's tubes on many occasions, but at increasing intervals during the next 12 months This lady died in May, 1912, very nearly three years after I was first called in to relieve urgent distress from a very large pleural effusion caused by cancerous metastasis During nearly the whole of this time the lady was able to get up to walk and drive about to meet her friends and to travel It is the most remarkable case of the kind that I have yet seen I have seen others where a pleural effusion due to malignant disease has not *recurred after one or more tappings* I mention this because I think the general impression is that the fluid re collects so quickly and so surely that it is hardly worth while to tap these patients, in many cases this is not so and the fact should not be assumed

The remarkable relief of pain of vomiting and of optic neurosis in cases of cerebral tumour afforded by *decompressing operations* is well known and I need only to mention it as one of the operations to be advised in cases of irremovable malignant disease

*The operation of lymphangioplasty has been in my experi*ence a disappointing procedure, and I doubt if it is worth doing

Diathermic Coagulation

By the use of an extremely rapid oscillating electric current in such quantity that it produces great heat the tissues can be immediately coagulated to a distance of half an inch or more from an electrode By this means we can remove sloughing and ulcerating growths without pain and
de should be in the form
tissues can be scraped or
under the anæsthetic or
can be allowed to separate The absence of all bleeding makes this method of removal much superior to all forms of curettage or cauterisation

There is probably a somewhat wide field for this modern application of electricity The current employed is very much stronger than has been used before for man, it can only be obtained where an alternating current is available, and where the services of an electrical expert can be obtained Such a powerful means of producing instant coagulation of tissue must of course be used with care and the ease with which it can be employed and its bloodless
ness make us unmindful of the limitations
must be its application

He considers also that the radio-activity of a mineral water may have an influence in the production of goitre. He believes that all goitrigenous waters are true mineral waters of a peculiar kind, and holds that their points of exit from the earth's interior—for such waters must come from great depths—are to be found in the lines of dislocation of the lithosphere, and by preference in the most recent or those which have not yet had time to become obliterated. He considers that these waters exercise on the general metabolism a powerful action of which the thyroid hypertrophy is only the reverberation. He bases his hypothesis on the work of Senator, Leopold-Lévi, de Rothschild, and others, who have shown that the thyroid mechanism controls the metabolism of lime. He explains the enlargement of the thyroid as an effort on the part of the gland to maintain, by augmenting its secretion, the chemical balance of the organism in the presence of a state of hypercalcification, induced by the use of water containing lime. His experiments on rats have confirmed him in this opinion. (Fig. 13.[2]) He has recorded that even heating the water to 100° C. for several minutes does not deprive it wholly of its goitre-producing properties. He believes prolonged boiling, or expulsion of its carbonic acid content, to be necessary to cause a precipitation of the dissolved salts on which, in his opinion, the goitre-producing properties of the water depend.

The views of *Répin* may be summed up thus: *That goitrigenous water is invariably mineral water; that in this water exists some chemical ingredient—possibly salts of lime and magnesium, possibly radio-active substances—which is the active principle in the production of goitre and resists a temperature of 99° to 100° C. for several minutes.* Now Wilms has shown that water raised to a temperature of 70° C. loses its toxic properties, and this result is in conformity with my own findings and those of Bircher, Breitner, Lobenhoffer, and others. But even if a temperature of 100° C. did not destroy the toxic agent of the disease, the fact would not exclude the possibility of an infective agent as the cause of goitre. I have, for example, isolated from the fæces of sufferers a spore-bearing bacillus which not only resists boiling for several minutes, but also exercises a curative influence on the disease when employed as a vaccine. The fact that Bircher has produced goitre in rats by means of water filtered through a Berkefeld filter might be quoted in support of Répin's views, but here again such treatment of the water is not sufficient to exclude the possibility of an infective agent, since this method of filtration does not render the water sterile. I am not prepared, therefore, to accept as final Répin's view as to the effect of heat on goitrigenous water.

Nor am I able to agree with his view that the goitre-producing properties of a water may be due to its radio-activity. Répin holds that goitrigenous waters are amongst the purest known, but he has advanced no bacteriological observations in support of a statement of such moment. The bacteriological researches of the Swiss Goitre Commission have proved that such waters almost invariably show an infinitely higher bacterial content than innocuous water, and we know that in radio-active waters the bacterial content is low. My own experience is in direct opposition to that of Répin, and exactly parallel to the results of the Swiss Commission. I am also informed by Professor Kolle that this Commission has failed to confirm in Switzerland Répin's supposition as to the radio-active properties of goitre-producing waters.

The lime and magnesium theory has already been dismissed as untenable, and in answer to the claim that goitre is due to the mineral character of the water, I have the authority of Dr. Cresswell Howell, of Bega, in New South Wales, for stating that goitre, to his personal knowledge, occurs in this locality, where the only source of water-supply is rain, while Veichardt mentions the case of the people of Eichstätt who are goitrous, though they drink rain water only. Similarly, in other goitre-infected regions the only drinking water is derived from snow, a fact responsible for the popular belief whereby goitre is attributed to the consumption of snow water. There are also recorded instances where the disease has arisen in persons drinking distilled water only. In this connexion I would refer again to the outbreak of goitre in the Bishop Cotton School at Simla, where whatever may have been the cause of the disease it certainly was not the water-supply, and this is only one of many similar instances with which the literature supplies us.

While, therefore, I would not go so far as to deny that the peculiar waters with which Répin is dealing may possess some quality which tends to excite the functional activity of the thyroid gland, it is immediately obvious that the explanation offered by him cannot be accepted as a complete and satisfactory theory of the origin of the disease.

Two main facts emerge from a study of the geological relations of the soil to goitre—viz., (1) that the disease appears to show a preference for certain soils; and (2) that it can, nevertheless, prevail on soils of any geological formation. Knowing, then, as we now do, that the essential cause of goitre is not a dissolved mineral ingredient derived from limestone soils, we must seek elsewhere an explanation for the connexion of the disease with the soil.

THE NATURE OF THE TOXIC AGENT OF GOITRE.

Such an explanation must involve some prior determination *of the nature of the toxic agent of the disease.*

Now the arguments upon which is based the explanation I have to offer rest upon a consideration of the behaviour of the endemic itself, upon deductions drawn from authenticated outbreaks, on my own observations in endemic centres, upon the conclusions to be drawn from the valuable work of Marine and Lenhart, who have studied the disease as it occurs in artificially bred trout, and finally upon my own experiments on man, and still more recently Bircher's on rats.

In a previous section dealing with the behaviour of the endemic we arrived at the conclusion that the evidence pointed to the existence of a living excitant. Nor can any other conclusion satisfy the difficulties presented by the outbreaks at Nagar and in the Boys' School at Simla, to which reference has already been made. To these instances I am able to add the experiences of Dr. Cresswell Howell, of Bega, in New South Wales. He has been kind enough to send me an account of an endemic of goitre in his district. The affected area is a stretch of undulating country about 30 miles long by 20 miles broad, and lies in a depression *among high hills. The prevailing rocks are granite.* The people are all of the farming class. The water-supply is rain water, which is collected from the roofs of the houses and stored in tanks. These tanks are only cleaned out on the rarest possible occasions. Dr. Howell informs me that he has examined the deposit in about 100 of these tanks and found it swarming with bacteria and animalcula of all kinds. A large number of young adults suffer from "a not very serious form of goitre." The swelling is invariably bilateral, gives rise to no pain, and rarely gives rise to symptoms. The goitre usually develops about the period of adolescence. Cretinism is also met with, but it is not of a severe type.

Here we have an endemic which, if it can be attributed to water at all, can only be due to the drinking of rain water which has become fouled by the washings from the dusty roofs and by its storage in dirty tanks. Clearly in this case, also, the disease is due to no dissolved ingredients, but to some living excitant, which finds in these tanks the necessary nutrient material for its life and growth.

Of my own observations, I will now direct your attention to those that deal with the village situated on the Gilgit Fan.

PREVALENCE OF GOITRE IN THE VILLAGES OF THE GILGIT FAN.

In the accompanying table I have indicated the prevalence of goitre in these villages, as determined by me in the winter of 1904. The figures are accurate, especially as

Village.		Population.	Houses.	Infected houses.	Per cent. of infected houses.	Per cent. of persons infected in infected houses.	Per cent. of total population goitrous.
1.	Basin	93	15	9	60 0	21·2	11·8
2.	Umphris ...	385	66	42	63·6	23·3	20 0
2A.	Damyal ...	181	30	20	66·6	30·3	18·8
3.	Majinpharri	718	108	68	63·2	24·2	20·0
4 and 5.	Ky-K	229	33	23	71·5	30·0	26·9
3A. 4A.	Sonyar ...	458	63	52	82·5	30 0	24·5
3, 3A. 4, 4A.	Kashrote ...	128	24	21	87·0	36 0	45·6

---

[2] This figure and Figs. 6, 7, and 8 will be printed together with others as a separate plate.

concerns children and males; but as concerns women I had often to rely on the statements of their male relatives as to whether they were goitrous or not.

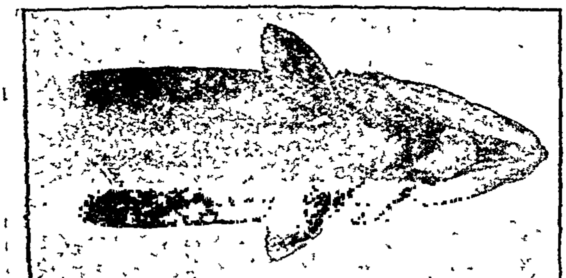
From this table it is seen that the percentage of infected houses, of infected individuals in these houses, and of the total population suffering from goitre, goes on increasing from the highest to the lowest village on the water-channels. In a paper which I read before the Royal Medical and Chirurgical Society of London in 1906, when describing the prevalence of goitre in these villages, I commented on the fact that where the polluted water of the main channel was joined by the purer supply from the Barmis spring the progressive increase of the disease was arrested.

The chemical composition of the water as it flows through the villages is the same as at its source. Only this difference could be detected in the water taken from the channel at Kashrote: it contained a larger amount of mineral matter in suspension, more vegetable débris, more amorphous matter, more animalcula, and on plate cultures it showed a much richer bacterial flora than the water at its source or higher up the kūl. It is, therefore, obvious that the increase in the disease bears a relation to the increasing organic impurity of the water, and we are again driven to the hypothesis that the toxic agent is a living excitant.

ENDEMIC GOITRE IN ARTIFICIALLY BRED TROUT.

Consistent with these conclusions are the deductions to be drawn from the paper written by Dr. Marine and Dr. Lenhart, and entitled, "Observations and Experiments on the so-called Thyroid Carcinoma of Brook Trout and its Relationship to Ordinary Goitre." These observers found that the so-called thyroid carcinoma was "severe endemic goitre." (Fig. 4.) Any peculiarity which the tumour in fish shows is due to the fact that the thyroid gland in fishes is not encapsuled, consequently as it enlarges it tends to grow into neighbouring structures.

FIG. 4.



Large external goitre in trout (Marine and Lenhart).

I shall now quote those parts of Dr. Marine and Dr. Lenhart's paper which have a special bearing on the present subject:—

> Our observations and experiments were made during October and November, 1909, at a large private fish hatchery in the mountains of Pennsylvania.
>
> The arrangements of the houses a
> This is shown in the figure (Fig. 5).
> series down the course of the broo
> simple. There is but a single spring supplying the upper six houses, while the lower five receive the water that has passed through the upper six, together with that from a second small spring and a 6 in. pipe line from a large stream about a quarter of a mile to the left.
>
> On account of the increased water supply, and for the clearer understanding of certain observations to be mentioned later, it is best to divide the series of tanks into an upper and a lower division. Between the upper and lower division of houses (that is, between Houses VI. and VII.) the water follows the original brook for a distance of about a quarter of a mile. Then it is again collected by means of a dam and enters the lower division of houses with the additions to its volume above mentioned. The water coming from the spring above all houses to the first house—a distance of about 50 yards—is also allowed to follow its natural bed. Apart from these two exceptions, the water is carried in covered raceways made of lumber.
>
> Houses I., II., III., and IV. contain 8-months' old fish. Houses V., VI., VII., and VIII. contain 1¾-year-old fish, and Houses IX., X., and the first pair of tanks in House XI. contain 2¾-year-old fish. The last pair of tanks in House XI. contains 1¾-year-old fish ...... the three most *important localities* as regards the effect of water-supply and water pollution are Houses VI., VII., and the last pair of tanks of House XI., which contain fish of the same age—that is, 1¾ years.

As a result of their examination of specimens of fish taken without choice from all the tanks, also specimens of different ages from the raceways above and below all houses, and lastly specimens of the larger 3¾-year-old fish from the trout stream near by, the authors concluded that:

> Fish which lived in the raceway above all houses and which have never been confined in the tanks maintain normal thyroids throughout their lives. Then, beginning with the series of tanks, it was shown that the 8-month-old fish are markedly affected even in the uppermost *of all the tanks*, and that there is a gradual increase in the degree of thyroid proliferation, which reaches its greatest extent and severity in the last house (VI.) of the upper division. Beginning with House VII.
> there is a marked improvement a
> proliferation coincident with the
> the probable purification of the w
> passage for a quarter of a mile alon
> improvement cannot be followed
> houses of the lower division, for th
> housed here, but the general impression is that *this improvement is* maintained throughout the remaining tanks to a gradually lessened extent. Lastly, the examination of the fish from the tail race, living wild, but in the polluted water, has shown that their thyroids are *normal in type*. Also examination of older fish obtained from both the tail race and the larger stream above the entrance of the tail race into it, have shown that, although the thyroid tissue has invaded all the structures beneath the pharyngeal mucosa at some past period of their lives, nevertheless, their stay of five to six months in a natural environment has effected a complete natural relief from the exciting cause or causes of the thyroid proliferation, and that the thyroids have resumed their resting or colloid state.

The authors conclude that "overfeeding, overcrowding, and a limited water-supply, are the major factors in the production of filthy, unhygienic tanks or ponds, and the unsanitary, unhygienic, and filthy tanks are in a very important but still unknown manner associated with the development of thyroid hyperplasia."

Gaylord's observations on goitre in fish are in complete agreement with the findings of Marine and Lenhart. He also has observed that where fish are confined in tanks situated one above the other, and through which the same water flows from one to the other, the prevalence of the disease increases markedly from above downwards. He gives the following table, which shows this increase:—

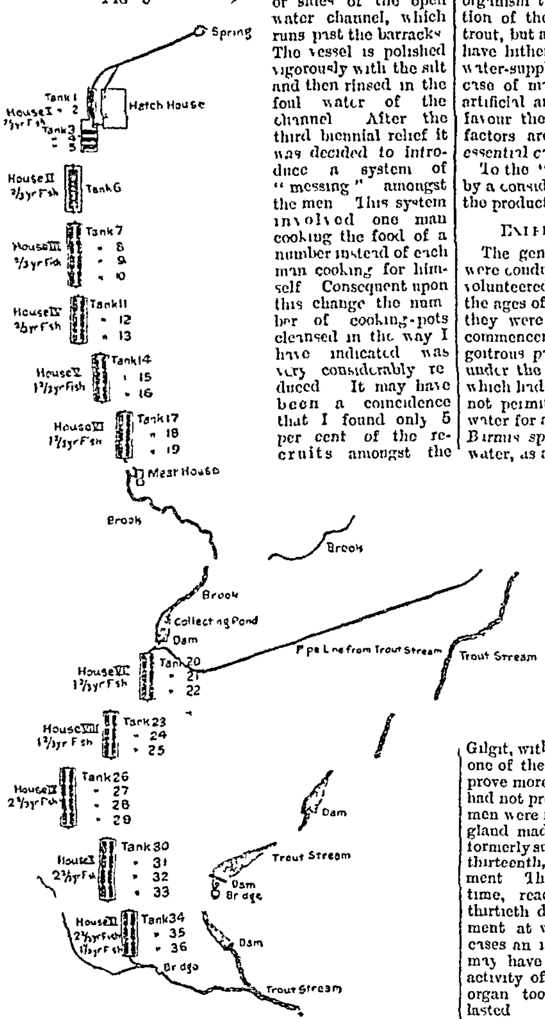
Water above the tanks	Fish goitre free.
,, in first tank	3 per cent goitrous.
,, in second tank	8 ,, ,,
,, in third tank...	45 ,, ,,
,, in fourth tank	84 ,, ,,

You will notice that the account of goitre in artificially bred trout corresponds in a remarkable way with my description of goitre in the eight villages of Gilgit, written in 1905. There is the same increased prevalence of the disease as the water becomes more polluted, and a diminution in the amount of the disease as a result of dilution of the impure water with the fresh spring water. The trout also conform to that striking characteristic of endemic goitre—viz., the capacity of spontaneous recovery on removal from the infected area. The markedly place-character of the disease, even in the case of these fish, is thus well illustrated.

Now, it is clear in the case of the trout that the influence of water in causing the disease cannot be doubted, and that whatever substance caused the disease remained behind in the tank. Anyone who has watched artificially bred trout in tanks will have observed their habit of "nosing" about the walls and bottom of the tanks. It is precisely in these places that suspended matter deposits itself. This deposit is made up of the remnants of food, and forms a nidus for the growth of numerous bacteria and animalculæ. I hold that it is in this deposit we must look for the causal agent of the disease, since it existed neither in the water flowing into the first tank, nor in that escaping from the last, in sufficient quantity to cause goitre.

Let us see what further evidence we have in this direction. I have stated that young soldiers who come to Gilgit frequently develop goitre within a few months. I have examined these soldiers for goitre on three different occasions, about six months after the biennial reliefs On he first two occasions it was noted that the recruits suffered o the extent of 20 to 22 per cent On the third occasion only 5 per cent were found to be goitrous Now, it is the custom of the men to cook their own food, and for this purpose each man is provided with a large assortment of brass vessels These he "cleans" by picking up a handful of silt from the bottom or sides of the open water channel, which runs past the barracks The vessel is polished vigorously with the silt and then rinsed in the foul water of the channel After the third biennial relief it was decided to introduce a system of "messing" amongst the men This system involved one man cooking the food of a number instead of each man cooking for himself Consequent upon this change the number of cooking-pots cleansed in the way I have indicated was very considerably reduced It may have been a coincidence that I found only 5 per cent of the recruits amongst the men goitrous, but I do not think so, and I am inclined to attribute the fall of the incidence of the disease from 20 to 5 per cent to a lessened infection from the soil by way of cooking-pots and infected hands which followed as a consequence of the "messing" system This system was, however, not popular amongst the men, so they reverted to their former habits of cooking, when I found that the percentage of goitre amongst the recruits again rose

FIG 5



Semi-diagrammatic drawing of the plan, arrangements and location of the hatchery, water supplies, houses, and retaining tanks (Marine and Lenhart)

Marine and Lenhart believe, as a result of their observations, that goitre is the *symptomatic manifestation of a metabolic and nutritional disturbance*, and that food is the major factor acting to bring about a fault of nutrition favourable for goitre development Comparing their results with the conclusions to which we have already been forced, we may admit that whereas a "metabolic theory" of goitre is not inconsistent with some of the facts, it fails to provide an explanation for all On the other hand, the "micro-organism theory" not only provides a satisfactory explanation of the development of the disease in artificially bred trout, but also of the experiments and observations which we have hitherto discussed While recognising that a limited water-supply in the case of fish, or a limited air space in the case of man, over crowding and over-feeding with a highly artificial and incomplete food, are factors which markedly favour the development of goitre, I am of opinion that these factors are of secondary importance only, and that the *essential cause of the malady is a living organism*

To the "micro organism theory" further weight is added by a consideration of the results of experiments directed to the production of goitre in man and in animals

EXPERIMENTAL PRODUCTION OF GOITRE IN MAN.

The general conditions under which my own experiments were conducted may be summarised as follows The men who volunteered for the experiments were young, usually between the ages of 18 and 25, they were newcomers to the district, they were under observation for some time prior to the commencement of the experiment, they lived in a non-goitrous part of Gilgit, not far from the village of Barmis, under the strictest guard, they were encamped on ground which had never been cultivated, they did no work and were not permitted to handle the soil, they were provided with water for all domestic purposes which was brought from the *Barmis spring at its point of exit from the hillside*, the water, as an added precaution, was boiled In no case was the restraint imposed upon the men broken through Water, purposely made muddy by agitation while flowing through its channel was brought daily from the village of Kashrote where goitre is very common It was filtered in large quantities through a Berkefeld house filter The deposit on the candle was washed off in distilled water, and a quantity of the dark grey mixture, equal to about 4 oz, was given to each subject in milk every morning before the first meal of the day

The first experiment was carried out in the spring of 1906 Six healthy young men, aged between 18 and 20, were the subjects Two of these had formerly resided in Gilgit and had suffered from small enlargements of the thyroid These swellings had disappeared on their leaving Gilgit, with the exception of a small nodule in the isthmus of one of them It was thought that these men were likely to prove more susceptible to goitrous influences than men who had not previously suffered from the disease The other four men were in all respects normal A swelling of the thyroid gland made its appearance in both of the men who had formerly suffered from goitre In one case it appeared on the thirteenth, in the other on the fifteenth day of the experiment The swellings fluctuated considerably from time to time, reached their point of maximum size about the thirtieth day, and then retreated to a point of enlargement at which they remained stationary In two other cases an increased pulsation in the vessels of the neck may have been the evidence of an increased functional activity of the gland, but no appreciable swelling of the organ took place during the 53 days the experiment lasted

In October of 1907 I submitted myself to the same experiment My house was situated in the Barmis village and my drinking water was the innocuous water of the Barmis spring Photographs indicate the change which was observed in my thyroid gland as a result of the experiment, which lasted one month The circumference of my neck increased by 2½ cm I first noticed the swelling on the fifteenth day of the experiment The enlargement fluctuated from time to time, as is observed to be the case in all commencing goitres

In the spring of 1908 the experiment was repeated in the case of six other young men in whom the thyroid was perfectly normal In two cases an appreciable swelling of the thyroid gland occurred which gave rise to an increase in the circumference of the neck in both cases of 1½ cm. In a third case the man was conscious of a sense of "fullness of the throat" at times; there was an increase of 1 cm. in the circumference of the neck, and throbbing of the vessels was from time to time observed. The other three cases showed no appreciable change during the 30 days the experiment lasted.

Coincident with this experiment six other young men living under precisely similar conditions were given, for a period of 30 days, the *boiled* suspended matter which had been separated by filtration from the muddied Kashrote water. It was subjected to boiling for ten minutes. Neither by manual examination, measurement, nor photography could an increase in size of the thyroid be detected in any of the six individuals.

Similar experiments were carried out in the autumn of 1907, with the exception that the residue in this case was not separated from the water by filtration, but the water was allowed to sediment and the deposit administered as indicated. Of 13 young men so treated, 2 developed slight enlargements of the gland which [illegible] while in 2 others a more pronoun[illegible] which was permanent.

Simultaneously with this experiment 13 other young men were given the Kashrote water sediment which had previously been *boiled* for ten minutes. It was administered at the same time and in the same doses. In none of these men could any reaction on the part of the thyroid gland be detected. The experiments lasted for 30 days.

In the spring of 1910 large quantities of the residue, separated from the muddied water of Kashrote by means of a Berkefeld house filter, were administered night and morning to 10 young men of the average age of 22. Of these, 4 showed no reaction whatever on the part of the thyroid gland during the 55 days the experiment lasted. One developed a slight enteritis on the fifteenth day, when the experiment in his case was discontinued. Well-marked changes were observed in the remaining 5 cases. In one of these, in addition to the complaints of tightness of the shirt collar [illegible] ement of the neck i[illegible] the measure[illegible] swelling was first noticed on the sixteenth day of the experiment, and the right lobe was more prominent than the left. The degree of enlargement can be well seen from photographs.

In a second case the reaction was more marked and resulted in an increased measurement of the neck of 2½ cm. The photographs of the case are especially good. (Figs. 6 and 7.) In a third case the swelling was more marked in the isthmus, which was felt as a rounded boss under the finger; it partially disappeared behind the sternum when the trachea was at rest. In a fourth case the circumference of the neck increased by 1½ cm., and in a fifth by 1 cm. In the first four cases the swelling persisted, in the fifth case it disappeared spontaneously, and while the patient was still drinking the residue.

Concurrently with this experiment 10 other individuals were given the same quantities of Kashrote water residue which had previously been *boiled*. Five of these men were selected as havin[illegible] of the thyroid. The duration of the [illegible] also was 55 days. In no case [illegible] [o]f the thyroid gland be d[illegible] [illegible]ion. In the five men wh[illegible] the original and final measurements of the neck were as follows:—

	cm.	cm.
(1)	34	3 ½
(2)	34	33
(3)	32	30½
(4)	35	34½
(5)	33½	33

These results show that the tendency to alteration in size of the thyroid was in the direction of diminution and not of increase.

All the cases of artificially produced goitre were rapidly cured by the administration of thymol.

The combined results of these experiments may be summarised as follows: 1. Of 36 individuals who consumed the untreated suspended matter of a notoriously goitre-producing water, 21 exhibited no change in the thyroid gland which could be detected clinically, 10 developed a notable enlargement, while 5 showed a swelling of the organ of a transitory character. 2. Of 31 individuals who consumed the same suspended matter, which had been previously boiled, none showed any reaction in the direction of increase in size of the thyroid.

In order to determine the effect of the administration of *filtered* water to selected individuals under the conditions of the experiments above quoted, I gave 7 men the filtered Kashrote water at the same time that 10 others were consuming the suspended matter separated from it by the Berkefeld filter. In 4 of these individuals the thyroid gland was perfectly normal on the date the experiment commenced; the other 3 were subjects of incipient goitres. All 7 drank only the filtered Kashrote water for 55 days. At the end of this time and during the course of the experiment, not only had no increase in size of the thyroid taken place in any of the individuals, but the existing goitres of the 3 men showed a considerable reduction in size. It is to be remembered that the suspended matter removed from the water by filtration had produced a thyroid swelling in 5 out of 10 individuals who consumed it while the subjects of the present experiment were [illegible]ed water.

With the exception of [illegible] filtered water—which, owing to the small number of men employed, I do not regard as wholly conclusive—these observations have been repeated sufficiently often, and the results have been so constant in character that I feel justified in drawing the following *conclusions*:—

1. Thyroid enlargement can be experimentally produced in man within a few weeks by the administration of the suspended matter separated by filtration *from goitre-producing waters*.

2. Thyroid enlargement cannot be so produced when the suspended matter is boiled.

3. The goitre produced in this way must almost certainly be due, not to the mineral, but to the living component of the suspended matter.

4. While it cannot be said to be definitely proved by these experiments that filtration through a Berkefeld filter wholly deprives the water of its goitre-producing properties, water so treated does not appear to be capable of causing goitre in man within a period of 55 d[illegible]

The results of th[illegible] days. [illegible] the observations I [illegible] these experiments an[illegible] [illegible]*ving excitant* have already quoted indicate that *the* [illegible] in com[illegible]*osit at the of goitre exists in greatest abundance in the d*[illegible] [illegible]*d other bottom and sides of water-channels, tanks, wells, an*[illegible] *receptacles of goitre-producing water.*

BIRCHER'S EXPERIMENTS.

I propose next to consider E. Bircher's experiments on rats. His results, published in various papers since 1909 up to the present time, may be summarised as follows:—

1. Goitre can readily be produced in rats by the natural water of goitre-producing springs.

2. The thyroid enlargement does not arise till after several months' subjection to the toxic substances contained in the water.

3. These toxic substances are destroyed by heat (boiling).

4. They are not removed from the water by filtration through a Berkefeld filter.

5. By centrifugalisation it is possible to render goitre-producing water innocuous.

6. The addition of certain chemical substances, such as hydrogen peroxide, to the water renders it harmless. (Marine and Lenhart have shown that the addition of small amounts of iodine, in the form of Lugol's solution, to the water causes a rapid disappearance of the thyroid hyperplasias of trout.)

7. Dialysis removes the goitre-producing substances from the water.

8. Substances separated from the water by the membrane of the dialyser are capable of producing the disease.

In his earlier papers Bircher has stated that the residue left on the candle of the Berkefeld filter after filtration does not cause goitre, but in his later papers (1911) he corrects *this statement*, and points out that while consumption of this residue for a period of nine months fails to produce any intense goitrous degeneration of the thyroid, goitres are produced after 12, 15, 18, and 20 months' consumption of this residue.

The photograph which I now show, and with which Dr. Bircher has been kind enough to provide me, illustrates these various methods of producing goitre in rats (Fig. 8).

Bircher's latest conclusions, as a result of his experimental work, appear to be that the water of goitrous localities derives from certain soils an organism which imparts to it a toxic substance of a colloid nature, and it is this substance that excit [illegible] He further believes that this [illegible] for the production of cretinism, [illegible] alone causes goitre. He bases this somewhat complicated conclusion on the fact that he and Wilms have produced goitre by means of filtered water. But, since the disease can also be produced by the residue on the candle and by the residue on the membrane of the dialyser, it appears to me to be simpler to conclude that the organism itself passed through the pores of the Berkefeld filter in their experiments.

It is well known that the passage of a water through a Berkefeld candle does not render the water sterile, and that the smaller bacteria (Schmidt) and ultra-microscopic organisms can find their way through it. This is particularly likely to occur when a filter is in constant use unless the candle is cleansed with care, and frequently boiled and renewed. Indeed, unless this is done it may become a source rather than a preventive of infection. Dr. Bircher has told me that a much longer period is required in which to produce goitre in rats by means of filtered water, a fact which appears to me to indicate that this method of filtration removes only a part of the goitre-producing substance. My experiments have shown that while the candle of a Berkefeld filter removed from the water a substance which caused goitre in 50 per cent. of men within a period of 55 days, the same water cleansed by this method of filtration failed to produce the disease in a limited number of men during the same period. It is possible, of course, that an organism living in water may impart to it toxic products, which, being in solution, will readily permeate the filter, but whether or not this is the case the organism which gives rise to such products must be regarded as the essential cause of the malady. Bircher's water is, in my opinion, inadequately filtered, and I must confess that for my own part until it has been demonstrated in man that adequate filtration fails to render a goitrigenous water innocuous I shall be unable to accept in their entirety the deductions of Bircher.

Bircher had produced goitre in rats only after the animals had been subjected for several months to the action of the excitant of the disease, while in men a reaction has been observed by me as early as the thirteenth to the fifteenth day. Now it is known that under natural conditions the disease can make its appearance in a much shorter time than several months—in a period, in fact, which corresponds closely with my findings in the case of the experimentally produced goitre of man. But this apparent difference is to be accounted for by the fact that the minute size of the lobes of a rat's thyroid would make the recognition of the earliest stages of the enlargement a matter of extreme difficulty. Indeed, unless animals were killed every day from the thirteenth day of the experiment onwards, it would be impossible to detect the beginning of the swelling. In man, *on the other hand, the larger size of the gland*, and the ease with which its changes in size can be appreciated by measurement and photography, make easy the recognition of the earliest signs of enlargement. Bircher was able, in the case of rats, to carry his experiments to a point which is not legitimately possible in the case of man. His goitres in rats are, therefore, relatively as large as those which are found in man after exposure to goitrous influences for a period of 12 months or longer. His results differ from mine only in this respect, that I have noted the earliest stages of the disease in man, while he was able to prolong the experiments [illegible] the residue [illegible] a Berkefeld filter, that he was able only to use a very few animals owing to the difficulty of procuring from the candle sufficient residue. In the case of my experiments in man I overcame this difficulty by making the water muddy at the time it was drawn, thereby obtaining a residue which contained the excitant of the disease in large amount. Considering the small amount of residue used by Bircher, the results produced thereby (Fig. 8) are very marked.

I consider, therefore, that Bircher's results in rats substantiate my previous findings in man, and that *the presence in suspension in goitre-producing waters of a living agent, which is the direct or indirect cause of the disease, has been demonstrated*; and with this conclusion Dr. Bircher has expressed to me his agreement.

The following are the characteristics exhibited by experimentally produced goitre in men.

(1) It usually appears about the fifteenth day of the experiment.

(2) It shows a marked tendency to fluctuate in size.

(3) It reaches its point of maximum size between the twenty-fifth and thirtieth day of the experiment.

(4) The enlargement of the gland is not great, nor is it progressive under the conditions of the experiment.

(5) It is accompanied, as a rule, with certain subjective symptoms of throbbing in the neck and feelings of fulness and discomfort.

(6) It may completely disappear under the conditions of the experiment.

SOIL A VEHICLE OF INFECTION.

Having, then, thus determined the toxic agent of goitre to be a living excitant, there remains the problem of the relationship of the disease to the soil.

The following are the facts which it is necessary to coördinate and explain:—

Firstly: The greater prevalence of the disease among the poorer, and especially the labouring classes, whose habits of life render them more susceptible to infections that lurk in the soil.

Secondly: It is a well-known fact that the inhabitants of country districts whose habits of life bring them into contact with the soil show a much larger percentage of victims than inhabitants of towns.

Thirdly: The extraordinary history of the disappearance and recrudescence of the disease in Martigny (Valais) requires some explanation other than the water-borne theory. The facts of this case as quoted by St. Lager are: "In the year 1818, owing to a great flood, the soil of the valley, which was moist and marshy, was suddenly covered by plant earth, to a depth of one metre, which had been carried from the mountains." As a result of this renewal of the soil, goitre and cretinism progressively diminished. Later these diseases again increased, due, it is stated, to the introduction of a new water-supply. It is not unlikely, however, that reinfection of the soil was largely responsible for its recrudescence.

Fifthly: There are the instances quoted by St. Lager and others to [illegible] of water rendered innocuous by [illegible] in itself sufficient invariably to [illegible] of persons resident in goitrous localities. We have also the authority of New Zealand physicians for stating that goitre prevails in parts of the North Island, where the only water used by the people of the district is that of the boiling springs.

Sixthly: I have the evidence of certain experiments which I am about to detail to show that mere boiling or filtering the water is not sufficient to prevent or cure the disease so *long as the possible avenues of infection from the soil are* not excluded. These experiments were conducted in 1904 and 1905. I assumed that if water were the only source of the disease, boiling and filtering ought to place sufferers in as favourable a position for cure as removal from the district, inasmuch as boiling is definitely known to render the water innocuous. Consequently, I selected a number of goitrous and non-goitrous individuals, to whom boiled and filtered water was administered for a period of two months. A second batch of goitrous and non-goitrous individuals was selected as controls, and these were allowed to drink the untreated water of the district. No restrictions were placed upon the men whose habits of life exposed them to continued infection from the soil. This experiment was carried out in one of the most goitrous villages in Chitral; and I am satisfied that the men drank only the boiled and filtered water provided for their use. It was repeated in Gilgit. I found as a result that neither boiling nor filtering the water sufficed to protect from the disease, nor did pre-existing goitres cease to increase in size.

The cumulative evidence of these experiments, together with the other facts and observations which have been dealt with in this section, affords, to my mind, conclusive proof of the proposition which I now lay down, that *soil is also a vehicle of the contagium vivum of goitre*.

Briefly, to recapitulate, we have now decided that the toxic agent of goitre is a *contagium vivum* conveyed by certain waters and contained in certain soils. I propose next to examine the peculiarities of the soil which favour its prevalence.

We have already remarked that limestone and lime-bearing rocks are those most commonly associated with the disease. Now these rocks are among the most porous as well as the most widely distributed of all geological formations. If, therefore, my deductions as to the nature of the disease are correct, these widespread and porous rocks would naturally provide its most normal habitat. The suitability of the soil does not depend upon its chemical composition, but rather upon its organic constituents. Kocher has drawn attention to the fact that in the neighbourhood of Bern, where goitre occurs, there is usually an abundance of organic matter in the rocks. The opinion of E. Bircher, expressed in 1908, that the nutrient materials necessary for the life of the excitant of goitre are derived from the remains of the extinct flora and fauna of marine deposits, though it points in the same direction, is one that is based on the slenderest of grounds. I believe that the presence in the soil of animal or vegetable matter, whether its deposition be remote or recent, may convert any soil, no matter what its geological origin, into a suitable habitat for the *contagium vivum* of the disease. A manure heap or a cesspit, for example, is much more likely to afford the necessary nutriment than the remains of the extinct flora and fauna, and is, indeed, a common source of such nutriment.

I am confirmed in this view by studies I have made of the topography of a large number of goitrous villages in Gilgit and Chitral, where I have observed that the presence or absence of goitre in a given village is largely a matter of the ease or difficulty with which the drinking water can become polluted.

I do not suggest for a moment that pollution *per se* is the essential cause of goitre, but I do suggest that pollution provides the nutrient material which admits of the life of the *contagium vivum* of the malady, not only in the soil, but in the water associated with it. On the other hand, a pure water is in itself antagonistic to the life of the living excitant, for we know that the addition of such a water to a goitre-producing one diminishes proportionally its harmful properties, while waters of known purity are frequently used as curative agents by sufferers from goitre.

It may be argued that if my contentions are correct all polluted waters should be a source of goitre. But this is no more a necessary sequence than that all polluted waters should cause typhoid fever. Indeed, the analogy between the spread of goitre and of typhoid fever is not inapt, so far as water as a vehicle for both these maladies is concerned. For the conditions which favour the life of the typhoid bacillus in water will favour also the life of the *contagium vivum* of goitre, and those precautions which have resulted in a great decrease of water-borne diseases, such as typhoid fever, have resulted also in a decrease of goitre. One not infrequently meets with reports in which enteric fever and goitre are bracketed together as having diminished in prevalence as a consequence of adequate protection of water-supplies. But just as a polluted water will not cause typhoid fever unless it contains the bacillus typhosus, so a polluted water will not cause goitre unless it contains the living excitant to which this disease is due. And as typhoid fever can be spread by agencies other than water—agencies which even two or three years ago were wholly unsuspected—so *we must recognise the probability of other sources of infection in goitre and not seek to explain every case by a slavish adherence to the "water theory" only.*

How any Water becomes Goitrigenous.

It is now easy to provide an explanation of the fact that a water which does not cause goitre in one place may become goitre-producing, or that a goitre-producing water may lose wholly or partially its noxious property. Since water picks up the causal agent of the disease from the soil it will pick it up only from those soils which contain it. A water which is organically pure may pass over such a soil and become goitrigenous as a result. The beneficial influence of adequate protection of water from the soil is exemplified by those many instances in which the simple canalisation of the supposed goitre-producing water has been followed by the disappearance of the endemic.

A water which has become goitrigenous may lose this property as a result of dilution with a purer water (examples of which I have brought to your notice) or by nature's usual methods of purifying water—the action of air and sunlight and by subsidence. The importance of the purifying action of subsidence and the rapidity with which it renders a water comparatively harmless are well illustrated by the case of the artificially bred trout. The water in the tanks was goitre-producing, but not the water which flowed into the first or escaped from the last tank.

A water may be conveyed in pipes for long distances and produce the disease among the consumers at a distance, provided it is goitre-producing at its source. Flowing rapidly through pipes, it is not subjected to these purifying influences to the same extent. Thus the water-supplies of towns which are derived from goitrous districts may give rise to the disease in the towns so supplied.

What, then, are the ideal conditions for the development of goitre? They are to be found in a country district with an agricultural population living on a porous soil, which soil contains much organic matter and by virtue of its porosity or slope admits of the ready passage of organic matter into the unprotected streams and wells that are the water-supply of the people. It is in mountainous countries where limestone rocks abound that these conditions are most frequently found in combination. Consequently, goitre is pre-eminently a disease of the hills, and its relationship to the soil is clear.

THE TREATMENT OF MENINGITIS OF OTITIC ORIGIN.[1]

By WILLIAM MILLIGAN, M.D.,

EX-PRESIDENT OF THE OTOLOGICAL SECTION OF THE ROYAL SOCIETY OF MEDICINE; AURIST AND LARYNGOLOGIST TO THE ROYAL INFIRMARY, MANCHESTER; HONORARY SURGEON TO MANCHESTER EAR HOSPITAL, ETC.

Of the various intracranial complications consecutive to disease of the ear there is no one which is at times more difficult to diagnose and up to the present more disappointing in its treatment than meningitis. Despite all that has been written, there is still considerable diversity of opinion as to what actually constitutes the condition, and perhaps even greater want of unanimity as to the exact relationship between lepto-meningitis serosa, so-called, and lepto-meningitis purulenta. While many observers look upon the former as the forerunner of the latter, others consider the two diseases as distinct entities, while there are still others who deny the existence of any such disease as serous meningitis (Körner, Luc).

That a type of otitic meningeal inflammation exists to which the name meningitis serosa may be fairly applied I have personally no doubt, and that it is the forerunner of all cases of purulent meningitis is a point I hope to make in the following argument. Clinically its presence is indicated by such symptoms as headache, vomiting, stiffness of the muscles of the neck, and increase of arterial tension. Upon tapping the lumbar theca the cerebro-spinal fluid spurts out under pressure. This is as a rule clear, although it may be slightly turbid, and it has a specific gravity of 1005–1008 and an alkaline reaction. It may contain a few lymphocytes and polymorphonuclear leucocytes. In the midst of such conflicting ideas it is unusually difficult to extract light from darkness, and I shall, I trust, be pardoned if in the following remarks I may appear to be didactic and to draw too much from my own, and therefore necessarily limited, experience. The subject is one, however, which has interested me very considerably, and with the surgical treatment of which I have had some little practical experience.

Considered from a pathological standpoint it is undoubtedly convenient to divide meningitis into such subdivisions as serous, plastic, fibrinous, and purulent; but from the therapeutic point of view these subdivisions are arbitrary and are merely so many phases in the evolution of a disease—a progressive disease—the outcome of bacterial invasion, whose invariable termination unless nipped in the bud is in the death of the patient. I would urge the importance of this view, and of recognising that there will always be inherent differences in the clinical landscape due to the variety and toxicity of the causal organism or organisms and the cell resistance of the individual. That the disease *is not necessarily fatal, provided that an early diagnosis is* made and prompt treatment instituted, is evident from the published records of carefully observed and authentic cases. The old adage that delay is dangerous is nowhere more applicable than in the treatment of otitic meningitis. Put briefly, successful treatment depends upon early diagnosis and early drainage. Special knowledge is required in order to make an early diagnosis, and courage to operate in the absence of the full *ensemble* of text-book symptoms.

---

[1] A paper read before the Otological Section of the Royal Society of Medicine on Jan. 17th, 1913.

What actually determines the onset of an attack of meningitis remains as yet undetermined. Why in meningitis is there an increase, and often a very rapid increase, in the amount of cerebro-spinal fluid? Why does not this increased exudate pass into the circulation, there to be dealt with? These and other such problems demand our most careful consideration. The mortality from purulent otitic meningitis is still so alarmingly high that any suggestions as to its treatment will be welcomed by all who have the progress of aural surgery at heart.

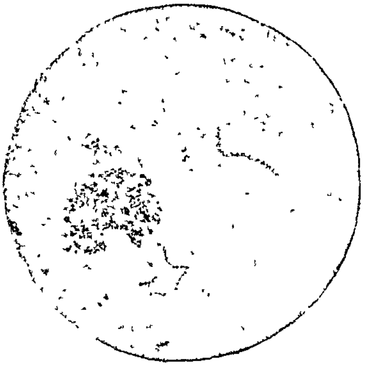
For practical purposes meningitis may be divided into two main types, (1) localised and (2) diffuse, and into subdivisions according as it attacks the external surface of the dura or the intradural spaces.

The treatment of that localised form known as extradural abscess is so well understood that I do not propose to discuss it beyond remarking that in my experience it is a more common complication of acute than of chronic otitis media, and more frequently found in the posterior than in the middle fossa, and also that I have frequently encountered such extradural collections of pus when their existence was quite unsuspected. It is quite a different matter, however, when ulceration of the dura has taken place and infective organisms have reached the intradural spaces. It is true that localised collections of pus are found in the intradural space, but the tendency here is towards generalised suppuration, as the defences thrown out by nature are rarely strong enough to resist repeated bacterial attacks. Such localised intradural collections of pus are rarely diagnosed, but are *occasionally found in the course of exploratory operations.*

Purulent lepto-meningitis, by which I mean an involvement of the meshes of the pia-arachnoid membrane, is by far the most formidable of the various intracranial complications secondary to purulent otitis media, and is frequently encountered with brain abscess or sinus phlebitis. For a time the infective process remains localised to the neighbourhood of the original focus of septic disease, but tends to become diffuse and generalised. The fact, however, that it remains for a time at any rate localised deserves to be more appreciated, for it is at this stage that operative interference is most likely to prove successful. Exacerbations of temperature denote to my mind invasion *of fresh areas of tissue, and, therefore, of an advance of* the disease, and are consequently important signals. It is useless to await the advent of all the classical signs and symptoms so ably portrayed in the majority of text-books. By the time they are in evidence the patient is, as a rule, [illegible] events, and an analysis of the cerebro-spinal fluid—the keystone to the situation—materially assist in making an early diagnosis and in instituting a rational line of treatment.

Under normal circumstances the mechanism controlling *the secretion of cerebro-spinal fluid and its ultimate passage* into the venous system is so delicately poised as to ensure an equable pressure. Let this mechanism be disturbed ever so slightly by factors which tend either to cause an increased exudation or to prevent the passage of fluid through the Pacchionian bodies and we have at once certain changes induced, changes which are capable of being accurately registered by modern chemical tests. Under normal circumstances the cerebro-spinal fluid is under slight pressure—20–30 mm. of mercury—has an alkaline reaction and a specific gravity of from 1005 to 1008. It may be secreted in great amount as the result of some peripheral focus of irritation, with as a consequence the various *signs and symptoms of increased intracranial tension; but so long as it* is able to deal with and to annihilate any bacterial attack it remains alkaline and more or less clear. Increased turbidity, however, does not mean that it has become septic, but that there has been a marked leucocytosis—in other *words, a supreme effort to ward off invasion. Diminishing* alkalinity denotes to my mind progressive bacterial invasion, while an acid reaction indicates that definite purulency has become established. My opinion is that all cases of purulent meningitis are preceded by a stage of serous meningitis, when a desperate fight is made by the meninges and cerebro-spinal fluid to resist bacterial invasion. To attain victory cerebro-spinal fluid has to be secreted in such quantity that the patient may become almost comatose from increased intracranial tension. If, however, operative interference be undertaken at this stage and the focus of infection removed with, at the same time, a fair amount of cerebro-spinal fluid, recovery not uncommonly follows. That the fight may be a long and desperate one is evidenced by the case of a female, aged 36, who for five weeks struggled against bacterial invasion of her cerebro-spinal fluid, and finally succumbed to a streptococcal infection. At the time of her admission to hospital she was suffering from suppurative labyrinthitis and symptoms of increased intracranial tension. Examination of the cerebro-spinal fluid, which was turbid, showed a marked leucocytosis, but no bacteria were found either in films or cultures. The fluid was under high tension, contained an increased amount of albumin, and reduced Fehling's solution normally. A complete labyrinthectomy was performed and a small extradural abscess at the apex of the pars petrosa opened. Later, on account of the persistence of increased intracranial tension, translabyrinthine drainage was instituted. The cerebro-spinal fluid which was examined from time to time remained turbid and alkaline until two days before the patient's death, when it suddenly became purulent and was found to swarm with streptococci and staphylococci. (Fig. 1.

FIG. 1.

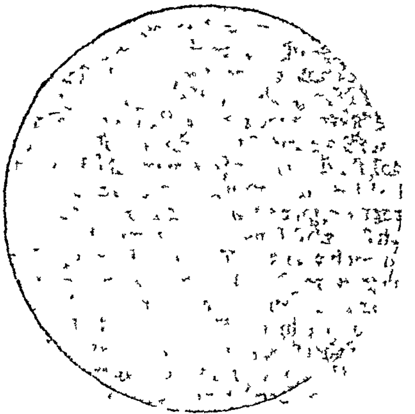


Suppurative labyrinthitis, suppurative meningitis. Film shows streptococci and disintegrated cellular elements.

Transition from the serous to the purulent type of cerebro-spinal fluid is not necessarily, however, indicated by the presence of bacteria. It may and does take place before any bacteria are discovered in films or cultures, as what we have *to deal with is the inter-reaction* between the toxic by-products of bacterial life and the living tissues. It is consequently to the chemistry of living tissues such as the cerebro-spinal fluid that we have to look to for the earliest indications of pyogenic invasion. Careful analysis will reveal delicate pathologi [illegible] anterior to that at which [illegible] s manifest themselves. [illegible] terial life is such as to destroy, or partially destroy, the existing carbohydrates or proteins in the cerebro-spinal fluid. It is now admitted that in normal cerebro-spinal fluid there is a carbohydrate—a glucose—which has the power of reducing the copper in Fehling's solution. In the presence, however, of bacterial infection of the cerebro-spinal fluid the existing carbohydrates become rapidly used up, with the result that in purulent meningitis there is an absence of this copper reduction. Hence we have at or [illegible] d apparently a certain test (Kopetzky)[2] of determining when and whether a serous meningitis is becoming purulent or not. In addition [illegible] creased, more especially the [illegible] g normal fluid a faint haze [illegible] is noted. In purulent [illegible] at times to as much as 0·1 per cent.

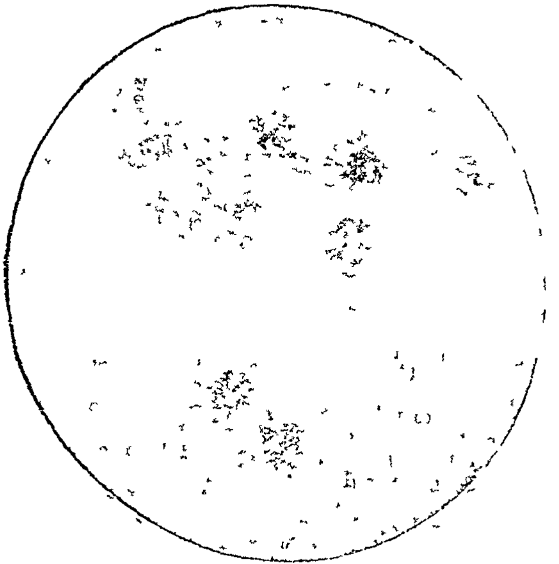
A progressive and at the same time diminishing alkalinity of the cerebro-spinal fluid, or a definite acidity, provides another useful bedside test of what is taking place. Several observers—among others Araki[3] and Zillehsen—have shown that in the presence of a lack of oxygenation there is a production of lactic acid in the living tissue. Where metabolism is upset as the result of some inflammatory, and more especially septic process—where, in other words, production is in excess of elimination—a varying amount of acidosis is induced, and it is to this artificial acidosis that the acid reaction of the cerebro-spinal fluid is due. So long as the cerebro spinal fluid remains alkaline, even though turbid, there is reason to expect a good result from operative interference, but should it become excessively turbid and acid the prognosis is grave, as then we know that the cell resistance of the individual has been overcome, and that bacteria and their toxins have gained the upper hand.

FIG. 2



Sarcoma of [illegible] Film shows [illegible]

FIG. 3



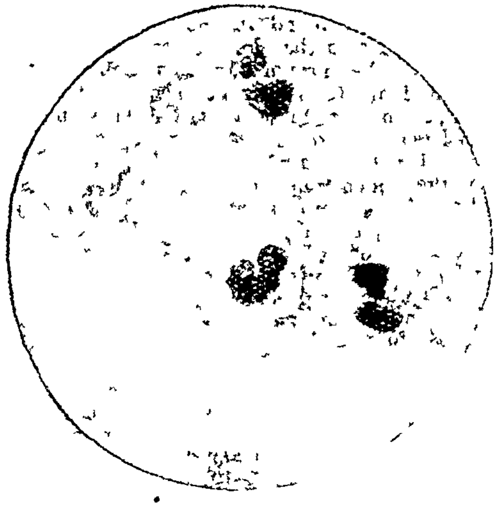
Temporo sphenoidal abscess, suppurative meningitis. Film shows leucocytosis.

In the early stages of meningitis the cellular elements found in the cerebro spinal fluid are very much the same as those found in the normal fluid. Occasionally a few lymphocytes in various stages of disintegration and a few polymorphonuclears are to be seen. Later on, when the fluid has become definitely purulent, there is an enormous increase in the number of leucocytes, chiefly [illegible] and a moderate increase in the number [illegible]

Bacteria are not found in films or in cultures in the early stages of the disease. As the disease progresses they are, as a rule, easily detected, either intra- or extra-cellular. The commonest varieties found are streptococcus, staphylococcus, a Gram-staining diplococcus, and Friedlander's bacillus. (Figs. 2, 3, and 4.)

Coincident with these delicate [illegible] fluid certain clinical signs and sy[illegible] make their appearance. Thus the gradual increase of intracranial pressure from excessive and protective secretion of cerebro-spinal fluid is accompanied by a simultaneous increase of general blood pressure and progressive tendency to cerebral anæmia. Owing to the brain substance itself being incompressible the pressure is exerted upon its vascular supply, with the result that nutrition is gradually cut off and a condition of malnutrition started. To this progressive increase of intracranial tension too much importance cannot be attached. It is in many cases the determining factor in the fatal issue, the cerebral anæmia which it induces paralysing the function of one or other of the sensitive vital nerve-centres. It is at this stage, the stage of active resistance by the cerebro-spinal fluid to the invasion of bacteria, when the fluid, although possibly turbid, is still alkaline and capable of reducing the copper in Fehling's solution, that lumbar puncture as a therapeutic measure is so advantageous. The withdrawal of a quantity of fluid, the amount varying with the pressure under which it escapes through the trocar, by relieving the mechanical symptoms due to increased pressure, tends to ward off profound cerebral anæmia and so to give time for the institution of more definite remedial measures.

FIG. 4.



Suppurative labyrinthitis, suppurative meningitis. Film shows leucocytosis, no bacteria.

Another indication of commencing meningitis is found in the presence of an œdema of the optic disc. The sheath of the optic nerve being a continuation forward of the membranes of the brain and containing cerebro-spinal fluid, anything which tends to increase the amount of cerebro-spinal fluid, and consequently intracranial pressure, will at the same time increase the pressure around the nerve, an increase reflected by a certain fluffiness of the margins of the disc.

I have also found in a few cases a lowering of the upper tone limit due to what I take to be similar mechanical causes. Owing to the fact, however, that the labyrinth upon the affected side is so frequently implicated in the primary septic process the test has in such cases to be applied to the labyrinth of the opposite ear.

The various chemical tests and the signs and symptoms just detailed are evidence of a *primâ facie* case of incipient meningitis and afford sufficient evidence to convict and to banish the invading party. To be effective, punishment should be drastic and rapidly carried out.

[2] Transactions of the American Laryngological and Otological Society, May, 1912.

[3] Zeitschrift für Physiologische Chemie, xv., 1891.

In the early stages of meningitis, when the cerebro-spinal fluid is under high tension, clear or faintly opalescent, alkaline in reaction, and on boiling capable of reducing the carbohydrates present, repeated or continuous drainage through the lumbar theca, in addition to the removal of the primary focus of infection, by so diminishing intracranial tension and consequent cerebral pressure may bring about a complete cure. Ventricular drainage, although it may find a place in the treatment of non-pyogenic meningitis, entails the risk of infecting a previously non-infected ventricle as well as the cerebral substance through which the knife or needle has to pass. Lumbar puncture is to my mind, however, much m[illegible] peutic measure, and although [illegible] bringing about a cure is not [illegible] tinuous lumbar drainage, which *a priori* might have been expected to be efficient, fails after a time, because as fluid is continuously withdrawn the brain stem sinks down into the foramen magnum, with the result that it is prevented flowing from the distended ventricles through the foramen of Majendie and so into the spinal theca. A more effective and more rapid method of drainage is necessary, such as is obtained by translabyrinthine drainage or by one or other form of decompressive operation.

The internal administration of urotropine is said to have a beneficial effect and to assist in keeping the cerebro-spinal fluid aseptic. It[illegible] and the fact th[illegible] after its admini[illegible] mouth, have given rise to the idea that it might possess a certain antiseptic value, in addition to which Barton[4] and Brown[5] maintain that it is also found in the secretion from the infected ear.

When in cases of serous meningitis the labyrinth is the primary focus of infection, its complete removal with, in addition, the establishment of translabyrinthine drainage as recommended by West and Scott,[6] may prove efficient. In preference, however, to translabyrinthine drainage, I am in favour of a decompression operation in the posterior fossa at some distance from the original focus of labyrinthine suppuration on account of the risks of infection of the cerebro-spinal fluid unless asepsis be maintained, which under such circumstances is extremely difficult, if not impossible.

Opinions differ very much as to the actual value of serum-therapy and vaccine treatment in cases of purulent meningitis. While not denying that the administration of an autogenous vaccine may help, my experience has been to regard it merely as an adjuvant and to rely upon the relief of intracranial pressure as afforded by one or other form of decompressive operation and the removal of the primary focus of infection.

To be successful, any treatment of otitic purulent meningitis presupposes elimination of the primary focus of infection, whether it be a middle or an internal ear suppuration, or, as is so frequent, of the two combined. It is only of late years that purulent internal ear disease has received anything like adequate attention. In my opinion the internal ear is not only by far the most frequent avenue of infection to the meninges, but is also the most dangerous because it leads to direct infection of the posterior fossa. In actual practice cases of what one might name [illegible] nearly as fatal as cases of [illegible] n the former the resulting [illegible] be localised, whereas in the [illegible] d diffusion, while from the [illegible] interference is considerably more difficult. The fact that in the posterior fossa there is a larger amount of cerebro spinal fluid to be infected than in the middle fossa adds to the danger of infection in this region. When therefore infection is by way of the internal ear, as can usually be established by the employment of the caloric or other labyrinthine tests, a complete labyrinthectomy, in addition to a complete post-aural operation, should be performed. Having eliminated the primary focus of infection any pathological tract leading into the interior of the cranium should be followed, and if a localised collection of pus be found, free drainage afforded by removal of as much of the surrounding bone as is deemed necessary. Assuming, however, that there is no evidence of any localised collection of pus but that we have to deal with a spreading meningitis the difficulties of treatment are enormously increased. The objects to be borne in mind after removal of the primary focus of infection are (1) the relief of intracranial pressure; (2) the establishment and maintenance of free drainage from the meninges; and (3) the overcoming of the existing toxæmia.

In undoubted cases of purulent meningitis lumbar [illegible] ian as a means of diagnosis. [illegible] operation is called for, the [illegible] o provide by a sufficiently free [illegible] re enough to relieve efficiently the [illegible] of [illegible] bee[illegible] are[illegible] practically to cork it up. Some operators content themselves with the making of such a window and with the relief of pressure thus obtained No doubt, in certain cases of i[illegible] this is sufficient, but i[illegible] the fatal issue for a f[illegible]

[illegible] he dura may be dealt with in several ways: (1) by excising narrow strips in parallel rows; (2) by raising as large a flap as the bone wound permits of; (3) by removing entirely the dura corresponding to the bone wound

To Charles Ballance[7] we owe the suggestion of attacking meningitis by the occipital route In 1891 he performed the now classical operation of draining the posterior subarachnoid space after trephining the occipital bone upon both sides of the middle line close to the foramen magnum.

In 1893 Alfred Parkin[8] proposed drainage of the cisterna magna, while in the same year Ord and Waterhouse[9] drained the posterior fossa after removal of a portion of the occipital bone and incision of the underlying membranes.

Since that time isolated cases have been recorded by various observers, some successful, many, however, unsuccessful from the fac[illegible] skilfully planned and exe[illegible] a stage, when in fact the [illegible] excessive intracranial pressure and progressive toxæmia.

Whether decompression be performed over the temporo-sphenoidal or cerebellar area great difficulty is encountered in dealing with the brain substance itself. The moment the dura has been incised the cerebral or cerebellar cortex, as the case may be, is thrust into the wound by the *vis a tergo*, and tends not only to cork up the opening made and so to prevent the escape of infected cerebro-spinal fluid, but also to [illegible] bone wound. [illegible] consequently [illegible] ain hernia is also encouraged, partly from the *vis a tergo* and partly from the mechanical difficulties of maintaining free drainage. To obviate this tendency to brain herniation Haynes,[10] of New York, has suggested drainage o[illegible] regards this situation as the *one logical place* where removal of infected cerebro-spinal fluid should be practised. The [illegible]

⅞ in. trephine is applied in the middle line about one inch above the margin of the foramen magnum and a disc of bone removed. The dura is then separated from the bone and two grooves made through the bone into the foramen magnum. When this triangular piece of bone has been removed the dura presents under pressure A small incision is made through the bulging dura and arachnoid with the immediate escape of cerebro spinal fluid. When a quantity of fluid has drained away the incision is enlarged and an inspection made of the posterior poles of the cerebellum, the notch between them, and the posterior surface of the medulla. A drain is then inserted into the cisterna magna and suitable dressings applied. So far I have only performed Haynes's operation twice, and in neither case did the patient survive. Both were advanced cases of purulent streptococcal meningitis with high arterial tension and pus-laden cerebro-spinal fluid; in both cases I believe the operation was undertaken too late. The procedure, however, appeals to me, and at some future date I hope to have success with a case undertaken at a much earlier stage of the disease. The position of the patient upon the operating table rather interferes with the administration of a general anæsthetic; possibly spinal anæsthesia might prove sufficient, but of this I have had so far no experience.

[10] Transactions of the American Laryngological and Otological Society, May, 1912.

My records show 37 cases of meningitis serosa, so-called, with 29 recoveries and 8 fatal cases. In these 8 cases the cerebro-spinal fluid became definitely purulent, and although one or other form of decompression operation was performed it was unsuccessful.

Of cases diagnosed at the time of admission to hospital or to the surgical home to be suffering from purulent meningitis and submitted to operation I have had 14. In 4 of these cases it probably would have been wiser to attempt no operation; at any rate, all died. Of the remaining 10, where there was at least a sporting chance of recovery, 6 died and 4, or 40 per cent., recovered. This certainly is nothing to boast of, but it is at least a step in the right direction.

In conclusion, I would urge the necessity of an early diagnosis, employing for the purpose such tests as I have detailed, followed by immediate operative interference should such tests prove positive. Although the results of surgical intervention as yet obtained are far from satisfactory, I believe the day is coming when with modern methods of diagnosis and technique at our disposal the high mortality of the past will shade into insignificance beside the brilliant records of the future. It is for a society such as this to lead in the van of progress, not to be deterred by failure, but to press on to attain that great reward—the knowledge that our efforts have been crowned with success, and that an otherwise doomed life has been saved as the result of scientific investigation and surgical skill.

I am indebted to my house surgeon, Dr. Frank Wrigley, for the preparation of the films.

Manchester.

ON A CASE OF ADENOMYOMA UTERI.

BY J. B. HELLIER, M.D. LOND.,
HONORARY OBSTETRIC PHYSICIAN TO THE LEEDS GENERAL INFIRMARY, AND PROFESSOR OF OBSTETRICS IN THE UNIVERSITY OF LEEDS;

AND

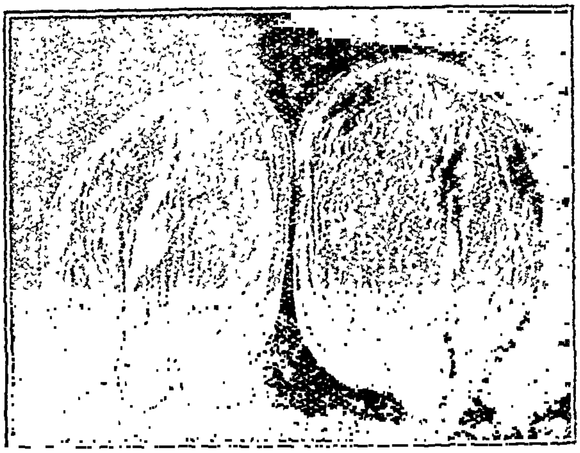
M. J. STEWART, M.B., CH.B. GLASG., M.R.C.P. LOND.,
CLINICAL PATHOLOGIST TO THE INFIRMARY.

THE specimen figured and described here was removed from a patient, aged 44, who was admitted for retention of urine. She was married at 23, but lost her husband two years later, and was never pregnant. She had always enjoyed good health. Her periods have always been regular, lasting four days, never excessive, though accompanied by some pain, but there has been no increase lately either in the frequency, amount, or painfulness of this function. Her first and only symptom was noticed on Oct. 13th, 1912, when she found that she could not pass urine. On admission a uterine tumour was found occupying the body of the uterus, which was about the size of a four months pregnancy. Supravaginal abdominal hysterectomy was performed on Oct. 19th. The operation was a little difficult because pelvic adhesions prevented the raising of the tumour, and because the tumour filled the pelvis it was far from easy to reach the attachments. Recovery was uncomplicated.

On section the tumour was found to be a typical adenomyoma. The uterine wall is uniformly thickened, and does not show the encapsuled growth or growths so characteristic of ordinary myomata. Hence it would not have been possible to treat this case by myomectomy. The uterine canal, as Fig. 1 shows, runs straight through the tumour without being deflected by any bulging growth; only at one point there is a small fibrous nodule well differentiated. The endometrium is somewhat thickened, and the naked eye perceives many larger or smaller cystic spaces scattered over the surface of the section.

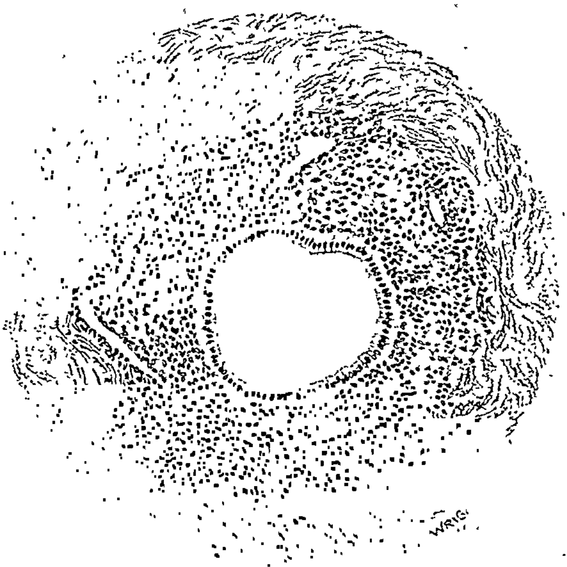
Report on microscopic examination by Dr. Stewart.—Diffusely scattered throughout the myometrium are numerous small cystic spaces of various shapes and sizes. These, on microscopic examination, are found to be lined by a broad zone of loose spindle-celled tissue closely resembling endometrial stroma, but innocent of glands. This is lined internally by a *single* layer of cylindrical and columnar epithelium, which in part appears to be ciliated. In many of the cysts only small tags of epithelium remain. Peripherally there is a fairly sharp line of demarcation between the endometrial lining of the cysts and the myometrium. (Figs. 2 and 3.)

FIG. 1.



Adenomyoma diffusum cysticum, from a photograph by Professor Hellier. Section of the tumour (macroscopic). Shows the uterine canal running straight through the tumour, diffuse myomatous growth of the uterine wall, especially of the posterior wall, and a small fibrous nodule about the centre; also several of the larger cystic spaces are very obvious. The tumour measures 4¾ inches by 3 inches.

FIG. 2.



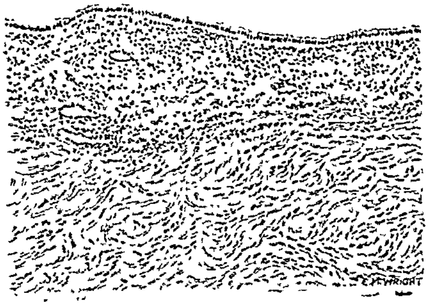
Section through one of the smaller cystic spaces. Shows a single lumen with a *lining* of columnar cells and surrounded by an endometrial-*like* stroma. The spaces in the latter are vascular and not glandular. Peripherally the unstriped muscle of the uterus is seen.

The condition appears to be one of adenomyoma diffusum cysticum, and the marked cystic distension of the endometrial down-growths (accepting Cullen's views on this point) quite accounts for the absence of actual gland-like acini.

Remarks by Professor Hellier.—Adenomyomata have been recognised as a group separate from ordinary myomata for several years. The first important publication on the subject was by Profes[illegible] in 1896, but we are indebted to a [illegible] by Dr. T. S. Cullen, of the Johns [illegible] for the best recent work on the [illegible] held that the gland structures are derived from vestigial remains of the Wolffian ducts, but Cullen has shown that the gland spaces can be traced to the uterine cavity, and that they are, in fact, offsets from the main uterine canal and communicate with it. It has been shown that menstrual fluid is excreted in these subsidiary glandular spaces, and that in one case, at least, the decidua of pregnancy has been observed in the glandular spaces.

Hence we have a very interesting conception of the uterus in this and similar cases, if we regard the corpus uteri as more or less penetrated in all directions by small diverticula from the central cavity, with an endometrial lining which takes part in the menstrual function and shares in the physiological changes of pregnancy.

FIG. 3.



A portion of the margin of one of the larger cystic spaces showing similar appearances to those in Fig. 2 (Figs. 2 and 3 are from drawings by Miss E. Wright.)

Amongst the clinical features common in adenomyoma Cullen mentions pain at the periods and marked menstrual excess, but this case shows that such features are not invariable. It also illustrates the fact, well known to gynæcologists, that retention of urine is often an important symptom in myoma uteri, and should always be thought of when retention occurs apart from pregnancy or other obvious cause. It is also an important indication for operating for the myoma. Some traces of old peritonitis were found in the pelvis, and this seems common in adenomyoma.

It seems possible, in view of the endometrial diverticula found in these cases, that an ovum might become embedded in the uterine wall and so give rise to an ectopic interstitial pregnancy at a point distant from the interstitial part of the oviduct.

Leeds.

DONATIONS AND BEQUESTS.—The late Mrs. Annie Ethel Perrin left for charitable purposes £16,000 divided into 17 parts, of which the Swansea Hospital, the Royal Ear *Hospital, London, the Bristol Royal Infirmary*, the Bristol General Hospital, the Bristol Dispensary, the Bristol Eye Hospital, the Bristol Hospital for Women, and the Bristol Deaf and Dumb Institution will each receive one part.—By the will of the late Mr. G. S. Guy the testator left £500 each to the Malvern Hospital, the Wolverhampton Royal Orphanage, and the Wednesbury District Nurses' Institution or Nurses' Home.—Mr. Austen Chamberlain has received a sum of £2004 from Messrs. F. and A. Swanzy, Limited, being their collection on behalf of the fund which is being raised for the extension of the London School of Tropical Medicine.—The Grand Duke Michael has sent a cheque for 500 guineas to the Hampstead and North-West London Hospital for the purpose of purchasing a motor ambulance.

HYPERTROPHIC STENOSIS OF THE PYLORUS IN ADULTS.

By H. GILBERT BARLING, M.B. LOND.,
F.R.C.S. ENG.,
PROFESSOR OF SURGERY IN THE UNIVERSITY OF BIRMINGHAM;
SURGEON TO THE GENERAL HOSPITAL,
BIRMINGHAM.

I SUPPOSE that most surgeons who have had to deal with cases of hypertrophic pyloric stenosis in the infant have wondered what happens to the muscular overgrowth in the pyloric canal, whether the patients are submitted to operation or recover without. Does the hypertrophy eventually recede or does it remain permanent? May it become exaggerated later in life and produce symptoms, or may it originate in adults? The following cases seem worth recording as a small contribution toward furnishing an answer to these questions.

CASE 1.—In January, 1909, a male aged 27, was admitted under my care in the General Hospital, Birmingham, with symptoms typical of pyloric stenosis—periodic vomiting of large quantities of fluid, evidence of stasis, loss of weight, and severe constipation. The illness began three years before admission with indigestion, which the patient described as pain in his stomach almost as soon as he had taken his food, a feeling of fulness, and much flatulence. These conditions would come on in attacks lasting two or three weeks, and were relieved by medicine. After an attack he would be all right, perhaps for two or three months, and would then have another similar attack. The pain was felt below the left costal margin; it would last from half an hour to an hour, and would gradually go off. When these symptoms had existed two years the patient began to vomit after taking food; at first it was usually after his midday meal, and the vomiting came on almost immediately after the food was taken; the vomited matter appeared to be the food very little altered. After the act of vomiting the patient felt quite comfortable and well. The intervals between the attacks of vomiting gradually became shorter, until eventually the vomiting occurred after taking even fluids. Blood had never been noticed in the vomit or in the stools.

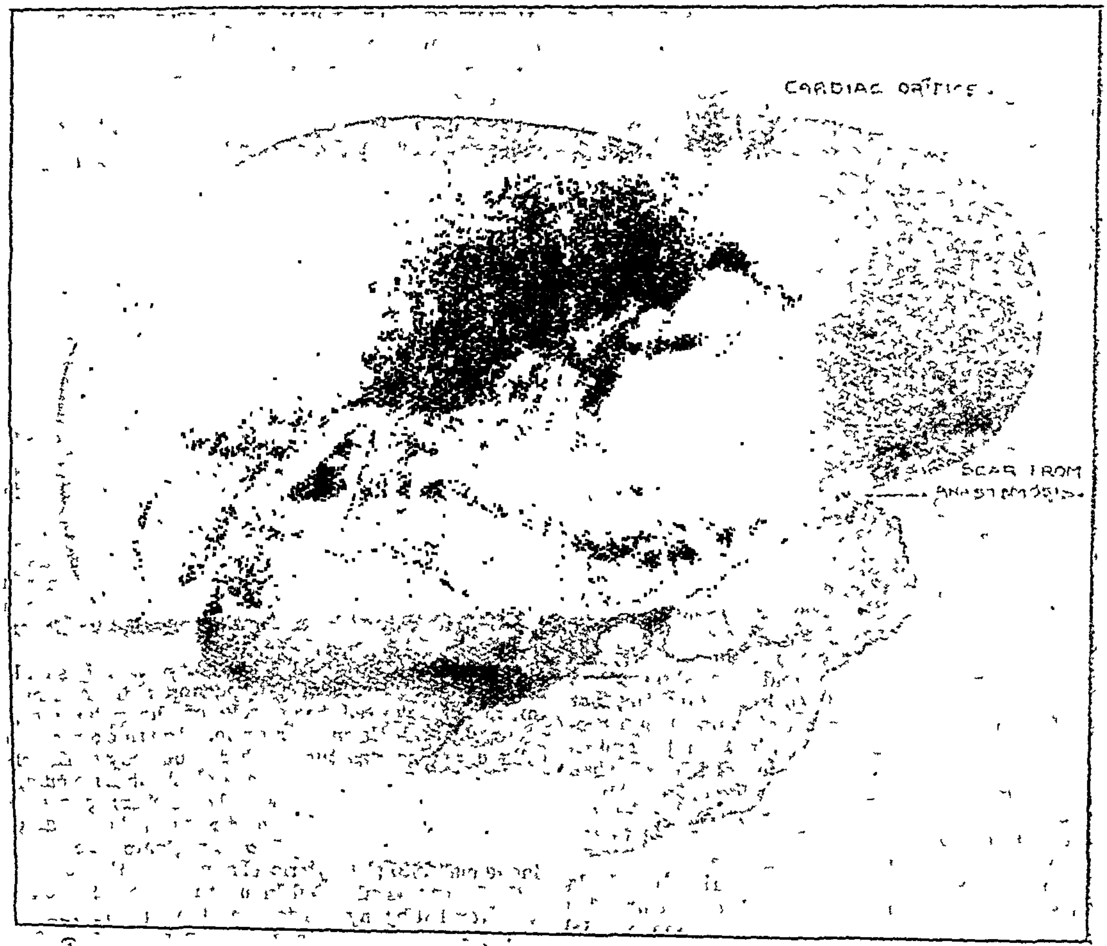
Operation.—The stomach was comparatively small, but its muscular coats were very hypertrophied. A firm, massive thickening involved the whole of the pyloric canal, and encroached a little on the antrum. The thickening felt like a solid muscular structure such as the body of the uterus; it was nearly three inches long and about an inch and a half thick; the peritoneum over the thickening was perfectly normal; the surface was smooth and without scar or nodulations. On attempting to invaginate the stomach or duodenum into the pyloric channel only the very tip of the little finger was admitted from either side. These conditions were verified by my assistant at the time of the operation, and we agreed that they could not be explained by any spasmodic contraction, nor did they suggest malignant growth or inflammatory formation, but rather an overgrowth of muscular or fibrous tissue. A posterior gastro-jejunostomy by the no-loop method was performed, and an easy recovery followed. I learn from Mr. E. H. Kenderdine, of Coventry, that the patient continues well and in full work—that is, nearly four years after the operation.

The conditions found suggested to me that the patient was suffer[illegible] to that which occur[illegible] recording the case, [illegible] examples of the same condition.

CASE 2.—Early in January, 1912, I was asked by my colleague, Sir Robert M. Simon, to see with him a girl, 17 [illegible] hospital, when she vomited after eating some fried fish; she was ill for a week, and then was able to return to work. A fortnight later the pain and vomiting after food returned and continued with intermissions until admission to hospital.

When admitted the pain came on from half an hour to an hour after food; the vomiting was frequent and was preceded by retching; blood had never been recognised in the vomited matter.

General state —The patient was thin and pallid; the cheeks were flushed; the left pupil was larger than the right; the mental state was dull, and she spent much time in sleeping The abdomen was scaphoid in shape and moved on respiration; tenderness on palpation was not elicited, and no tumour could be recognised; the bowels were very constipated A test meal showed the presence of unaltered currants and muscle fibre some six hours after the meal was given The vomited matter was generally very disagreeable in odour, but repeated examination failed to show the presence of blood. A bismuth meal administered for X ray examination was vomited almost immediately. Von Pirquet reaction was negative; the leucocyte count was 10,000 The temperature was irregular; sometimes it ran up to as high as 103°F.; the pulse was irregular and generally quick. The girl was evidently very ill, more so than one would generally expect to find in a case merely of simple stenosis of the pylorus, and both Sir Robert Simon and myself thought, from the character of the vomit and from the patient's general condition, that it was possible she was suffering from a stenosis in the small intestine rather than at the pylorus, and we were suspicious that the condition might be one of tubercular constriction from past ulceration of the bowel.



Sketch of stomach and duodenum, laid open to show hypertrophic stenosis of pylorus.

Operation (Jan. 15th) —The pyloric canal presented a [illegible] limited at both ends and resembling [illegible] stenosis of young infants. The [illegible] quite smooth and free from any indication of ulceration; there was no nodulation and no fixation on adjacent parts. The usual operation of posterior gastro-jejunostomy was performed. The operation was well borne, but on Jan. 17th a slight convergent strabismus was noticed, and the patient complained of diplopia On the 19th she had vertical nystagmus, and on the 24th complained of pain in the right side of the abdomen, and a little blood was noticed in the urine; the blood increased in amount the next day or two. On the 26th optic neuritis was observed, and on that day tubercle bacilli were found in the urine Vomiting did not occur for the first few days after the operation, but subsequently it happened at rare intervals. The patient died on Jan 31st apparently from tubercular meningitis. No complete necropsy was allowed, so the stomach only was examined

For the illustration I am indebted to my dresser, Mr. Oscar Parkes It shows the first part of the duodenum, the pyloric canal, and the adjacent part of the stomach laid open; the overgrowth of tissue in the pyloric canal and its abrupt limits are well seen. Careful examination of the exposed mucous membrane showed no trace of old or recent ulceration, and microscopic section revealed only an overgrowth of the circular muscular fibres. The thickening of the pyloric canal in the first case was much more marked than in the second, and allowing for the difference in size of the organs compared, it was an exaggeration of the infantile condition

When operation revealed the cause of the patients' symptoms the near relatives of each patient were carefully questioned as to the history during infancy, but no facts were obtained suggesting the presence of stenosis in the patients' lives at an earlier date than that recorded in the preceding notes.

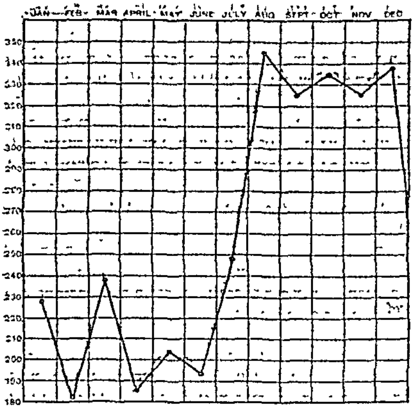
Birmingham.

MALARIA IN INDIA AND THE BIRTH- AND DEATH-RATE.

BY W. H. KENRICK, M.R.C.S. ENG., L.R.C.P. LOND.,
MAJOR, I.M.S.

DEALING first with the birth-rate, malaria in both its *epidemic and endemic forms has a very marked effect.* In the case of the epidemic form of the disease this is shown by a great reduction in the total number of births in the year following the epidemic. This reduction begins nine months after the commencement of the epidemic, and reaches its height exactly nine months after the epidemic attains its maximum. This is well shown in the monthly birth curve of the Punjab for the year 1909, following the severe epidemic of the previous year, [illegible] sudden fall spread [illegible] its *maximum in J*[illegible] alone; it is quite [illegible]

FIG. 1.

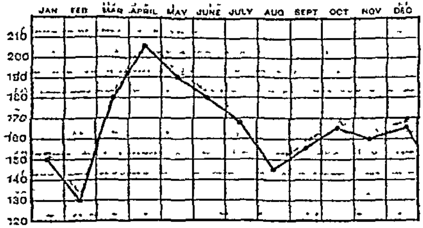


Birth curve of 34 healthy villages, with an average spleen rate of 4 per cent.

by famine, cholera, plague, &c., and enables the course of an epidemic in a province to be mapped out by a study of the birth statistics only.

Endemic malaria, on the other hand, causes no reduction in the yearly birth-rate of places in which it prevails, compared with the rate of neighbouring healthy areas. It has, however, a marked effect upon the monthly distribution of births. If the average monthly curve of a healthy area for a series of normal years is drawn, it is seen that the births are least in number during the early months of the year and greatest during the autumn months, the highest point of the curve generally being in October or November. The probable reason for this is that since the early part of the year is the most healthy, and at the same time the period of the harvest—in other words, a time when the physical and economic condition of the people is at [illegible] most favourable for [illegible] on the contrary, the [illegible] which fever is most [illegible] every inhabitant is chronically infected with the parasite, and frequent *exposure to the often severe cold of this period readily* induces relapses. Thus during the cold weather months there is an increase of malaria, and, as the results of *epidemics show, a period of increased fever prevalence is a* period of comparative sterility. The rise in the birth curve, which normally should occur in the autumn, is thus postponed for five or six months, and takes place during March, April, or May instead. This is well shown in the diagrams (Figs. 1 and 2), which give the birth curves of two groups of villages, in each of which the amount of malaria actually present was determined by measurement. The birth curves of several "thana" (police registration) areas, in a part of the Central Provinces of India well known [illegible] statistical administrative units, and the registered births for a consecutive series of years (1901–09) are taken. The healthy and malarious tracts alike are inhabited by the same *class of people, living under practically similar social,* economic, and climatic conditions. The only difference between them is in physiographical features, which in the [illegible]s, forests, rank grass, &c.) as [illegible] with intense malaria. The [illegible] of the two types of birth curves can only be attributed to the effects of this chronic disease.

FIG. 2.



Birth curve of 33 hyperendemic villages; with an average spleen-rate of 80 per cent.

With regard to the death-rate, it is known that malaria [illegible] which it is endemic; but [illegible] (in the tropics) are usually [illegible] and apathetic, and their vital statistics, so far as *causes* of death are concerned, unreliable, the proportion of the total mortality attributable to this disease cannot, as a rule, be ascertained. In certain cases, however, detailed measurements have been made to ascertain the malarial mortality. Rogers found that 25 per cent. of the total fever mortality in a highly malarious district of Bengal might be ascribed to malaria; and Ross estimates the true malarial death-rate of Mauritius to average about 20 per 1000 per annum. In parts of the Central Provinces of India endemic malaria is extremely prevalent, an average spleen rate of between 80 and 90 per cent., with a high [illegible] among the inhabitan[illegible] of such endemic areas during a period free from cholera, plague, and famine are closely compared with those of neighbouring healthy areas under similar conditions, and [illegible] villages (average spleen-rate 4 per cent., 727 children) compared with a group of 33 hyperendemic villages (average spleen-rate 80 per cent., 840 children):—

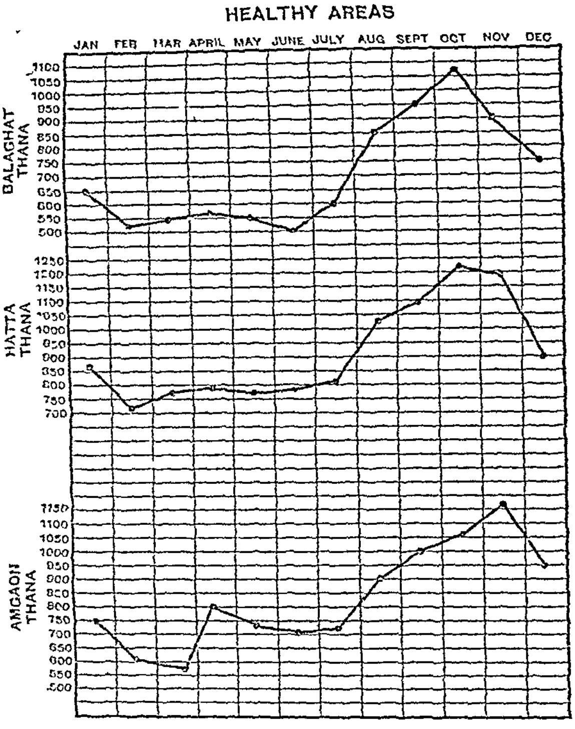
	Death-rate per 1000.		
	1908.	1909.	1910.
1. Group of healthy villages	24	22	33
2. Group of hyperendemic villages	38	32	44

The existence, therefore, of malaria of a hyperendemic nature in the one tract caused an average increase of 12 per 1000 in the general death-rate.

It is the custom for the village registration agency in India to return from 70 to 78 per cent. of all deaths occurring in hyperendemic areas as "due to fevers"; verification of 300 of these deaths showed that 50 per cent., or 38 per cent [illegible] ascribed to malaria. [illegible] as 35 per [illegible] per 1000, w[illegible] 1000—by which the death-rate of a malarious locality [illegible] that of a healthy one.

The mortality of malaria falls most heavily on the young, children aged from 2 to 8 years being the greatest sufferers (the earliest case of infection which came under my observation was an infant aged 4 months); and there is evidence to show that it rises *pari passu* with the endemic index.

FIG. 3.



Birth curves of healthy registration areas in a district of the Central Provinces.

Further investigation into these questions is desirable. With reference, however, to the restricted area concerned in these observations, the following conclusions may be drawn: 1. Epidemic malaria causes a marked fall in the birth-rate of the following year, chiefly noticeable during the months of June and July. 2. *Endemic* malaria, while not influencing the annual birth-rate, has a marked effect upon the seasonal distribution of births. 3. The malarial mortality of hyperendemic areas amounts to at least 13 per 1000 per annum.

Birth curves of malarious registration areas in the same district shown in Fig. 3.

A PRELIMINARY COMMUNICATION

ON

THE PATHOGENICITY AND VIRULEN OF BACTERIA.[1]

BY F. H. THIELE, M.D. LOND., M.R.C.P. LOND.,
LECTURER IN BACTERIOLOGY, UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL;

AND

DENNIS EMBLETON, M.A., M.B. CANTAB.,
ASSISTANT LECTURER IN BACTERIOLOGY, UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.

(*From the Bacteriological Laboratory of University Coll Hospital Medical School, London.*)

As much of the work on which this paper is based has yet been published it is necessary briefly to review the w in order to bring out the argument clearly. First, then, must consider the mechanism of fever production.

Friedberger showed that in animals which have b sensitised with serum (for the demonstration of anaphyla a much smaller dose of the protein is necessary for the duction of temperature variations than is necessary unsensitised animals. He also showed that in the ea stages after sensitising an animal a further dose of a prot will produce a rise of temperature, but later on the *same* d will produce a fall of temperature. Finally, he showed t if anaphylotoxin be prepared *in vitro*, a small dose injec into an animal will produce a rise of temperature, a lar dose a fall. From these observations he concluded that th various effects were due to the formation of anaphyloto produced *in vivo* on the one hand and *in vitro* on the oth and that the various effects depended on the amo exhibited.

Vaughan and Wheeler have shown that repeated doses protein or bacteria produce temperature variations, type of variation depending on the dose and frequenc inoculation. They consider that protein and bacteria cont a preformed toxic molecule.

Hort and Penfold have shown that temperature variati occur in animals when these are inoculated with cert bacteria. They consider that the temperature variations due to a substance they designate pyrogen, which substa is supposed to be liberated from the medium on which bacteria are grown.

We have been able to show the following.

1. Given a sufficiency of ferment in an animal, vary quantities of protein or bacteria will produce, when inject the following conditions :—

(*a*) A sufficiently small dose = no temperature variation.
(*b*) A larger dose = a temperature rise.
(*c*) ,, ,, = a greater rise.
(*d*) ,, ,, = less temperature rise.
(*e*) ,, ,, = no temperature variation.
(*f*) ,, ,, = a temperature fall.
(*g*) ,, ,, = a greater fall followed by death.
(*h*) ,, ,, = acute death, so called anaphylax

If, however, there is insufficient ferment present to s with, acute anaphylaxis can never be produced, and so on

2. Proteolytic degradation bodies, so-called anaphylotox manufactured *in vitro* produce effects parallel to the ab according to the dose.

3. That by producing varying stages of anti-anaphyla (that is to say, the condition following the anaphyla shock in which recovery has taken place), the conditi following a further dose depend on the amount of ferm used up by the first dose. Friedberger came to similar c clusions from his work. For example, if all the fermen used up by the first dose the second dose produces no te perature variation. If most of the ferment is used up second dose produces a temperature rise. If little fermen used up the second dose produces a temperature fall.

4. By inoculating the tissues of animals sensitised protein or bacteria into a normal animal, that these passiv sensitised animals acquire the power of developing te perature variations after injection of the specific protein.

And we were able to show that if the amount of fermen i.e., the sensitised tissue injected—were kept constant, temperature manifestations varied inversely with the amount of the protein subsequently injected, and by keeping the protein constant and the ferment variable similar results were obtained. Also, if normal tissues of animals were injected into normal animals, these animals developed the power of giving temperature variations with smaller doses of any protein than normal animals, this power being due to an increase in the normal ferments, specific or non-specific.

---

[1] A paper communicated to the Royal Society of Medicine Jan. 21st, 1913.

From these observations we have been able to deduce:—That temperature variations are due to the interaction of the substance injected and the ferments present normal or induced. That the substance which gives rise to the temperature variations is an early degradation product of proteolytic disintegration of the injected substance. That the rise and fall are both due to the same substance and not different stages of degradation of this substance, but to its rate of accumulation. The substance in large amounts produces a fall of temperature, in small amounts a rise; so that the results depend on the relative amounts of substance injected and ferment present. If, then, there is sufficient ferment present, any stage can be produced from a single dose, according to its size, from a temperature raising effect, through a temperature depressing, through so-called anaphylaxis to the acute Auer Lewis phenomenon or acute anaphylaxis.

The toxicity of bacteria not possessing an exotoxin was formerly considered to be wholly due to the liberation of an endotoxin. Friedberger considers that toxicity is due to the formation of anaphylotoxin from the endotoxin, but does not absolutely deny the possibility of the endotoxin being directly toxic. Now, the views held at present with regard to the endotoxin are that it is (1) a toxic substance secreted in the animal body; (2) a preformed toxic molecule which is liberated by breaking up of the bacterial cell (*a*) in the animal body by antibodies, (*b*) *in vitro* by alcoholic potash, (*c*) *in vitro* by watery potash, (*d*) *in vitro* by freezing and thawing or by freezing and grinding.

We have been able to show that the so-called endotoxin is really the toxic proteolytic degradation-bodies liberated from the bacterial protoplasm by the action of the tissue ferments, and that accumulation of this body in bacterial infection is the cause of the symptoms and death, and is the same for all bacteria, and that this is the same substance obtained by Friedberger *in vitro or from the peritoneal cavity, using the* peritoneal cavity as a test-tube.

We conceive that the toxicity of a bacterium depends upon [illegible] protoplasm easily, the toxic substance is liberated readily, and the symptoms depend on the amount of accumulated toxin at any given moment. On the other hand, if the bacterium is tough, for example, the tubercle bacillus with its fatty capsule, the ferments can only act on it very slowly, and consequently the rate of production of toxin is very much slower. Again, within limits, an increase in the ferment will increase the rate of liberation of toxic material from the bacterial protoplasm.

It is said that an animal dying from any form of bacterial infection is supposed to die from the specific poison—i.e., the endotoxin. Now we have been able to show that the blood of these animals contains an intensely toxic substance, which when inoculated into guinea-pigs intravenously in doses of from 5 c.c. to 10 c.c. produces acute death with the typical symptoms and post-mortem appearances of proteolytic degradation body poisoning. We have obtained this syndrome with the blood of rabbits dying from chicken cholera, coli, danysz, dysentery, and phlei, and the blood of guinea-pigs dying from staphylococcus, tubercle, proteus, and prodigiosus. We have also produced the same syndrome with the blood of animals which have died of toxæmia from the above-mentioned dead bacteria. The number of bacteria inoculated with the blood of these animals is extremely small, and is quite insufficient in itself to cause acute death of the type mentioned. In fact, we have shown that when bacteria are completely broken up by freezing and thawing or by grinding, so as to liberate the "endotoxin," death of this description only rarely occurs, and then with quantities of over 20 mgm. dry weight. We have succeeded in producing acute anaphylactic death with tubercle bacillary emulsion (B.E.), coli, and proteus. With all other organisms with large quantities intravenous injection causes delayed death (delayed anaphylaxis). The animal develops rigors, ruffling of the coat, fall of temperature below 94° F., paresis spreading from the posterior to the anterior extremities, and disordered respiration. On death the post-mortem changes are all the same—viz., congestion of the right side and veins, distended gall and urinary bladders, and a certain degree of lung distension. Now these symptoms and post-mortem appearances are identical with those produced by inoculation of egg albumin into egg sensitised guinea-pigs, in doses too small to cause acute death (or where the ferment is insufficient to cause acute death). Now we have noticed that guinea-pigs dying of any bacterial infection die with these same symptoms and post-mortem appearances. The results obtained by Arima with so-called typhoid toxins—i.e., the soluble and insoluble typhoid protoplasm—are identical with these. Vaughan and Wheeler have produced tissue changes in animals by the repeated inoculation of egg albumin which are exactly the same as those produced by bacterial infections.

Thus we see that the toxic substance liberated from bacteria in large quantities produces in normal animals symptoms of acute proteolytic degradation body poisoning, in smaller quantities great fall of temperature, paresis, rigors, &c., in smaller quantities still fever; and that the so-called endotoxins only give rise to those symptoms when the various ferments have been able to produce the necessary accumulation of degradation bodies to give rise to the symptoms. In animal infection the difference between the symptoms produced by the different bacteria depends on the distribution, rate of multiplication, and consequent liberation of the degradation bodies. For example, a characteristic clinical picture may be obtained with certain bacteria due to local cumulative effects. In certain structures *where the organism is normally present* in large quantities, and is continually there undergoing proteolytic degradation—for example, in the intestines—we always note in coli infections intense hyperæmia of the mucous membrane and hyperæmia of Peyer's patches in guinea-pigs.

A similar condition was noted by Schittenhelm in dogs, by injection of hydrolytic degradation products of bacilli coli. The acute toxic material of Vaughan and Wheeler, Schittenhelm, &c., are really early hydrolytic cleavage products and not unaltered bacterial protoplasm.

Friedberger, in his paper on anaphylatoxin fever, drew attention to the similarity between certain features in the syndrome of bacterial infection and those produced by anaphylatoxin.

To summarise. 1. Endotoxin as originally understood does not exist. The bacterium does not liberate a primarily toxic substance. 2. The bacterial protoplasm itself is not directly toxic. 3. The bacterial protoplasm becomes toxic on exposure to ferments. 4. The degree of toxicity depends on the accessibility of bacterial protoplasm and concentration of ferment. 5. As we shall show later, if the amount of ferment is very large, lysis occurs so rapidly that the bacterial protoplasm is broken down to non-toxic substances.

Now with regard to the ferment and its formation. Working on the early stages of the formation of a hæmolytic antibody in rabbits to human red cells, the development of the specific antibodies can be traced through the following stages from the panenzyme. Complement in its simplest form must be regarded as panenzyme, which will attack any form of protein, though slowly. In its earliest stage the specific ferment occurs in such a condition that when exposed to the specific antigen at 0° C. it combines with it, and it is found that the complement, which would otherwise activate sensitised homologous antigen, has been removed, but that the other complements are left free. This ferment is destroyed by heat at 56° C., and cannot be reactivated by the addition of fresh complement. The next stage is the development of a thermolabile amboceptor, which combines at 0° C. and does not fix complement in the cold and by itself will agglutinate. The final stage is the development of the thermostable amboceptor. In the normally occurring hæmolytic antibody (e.g., in rabbits to sheep's red cells) all three stages may be demonstrated to occur at the same time, and it seems that the younger the animal the less differentiated the ferment is. The antibodies to bacteria apparently go through the same stages, but it is only in certain cases that the whole process can be traced.

Thus we consider that the complement is an enzyme, and the amboceptor is a kinase or coënzyme which activates and adjuvants the former.

From the above work we thought that organisms were not pathogenic because they produce endotoxin, but were pathogenic to animals because the animals had ferments which were capable of acting on the bacteria so as to cause an accumulation of proteolytic degradation bodies, which would inhibit phagocytosis and allow the bacteria to multiply.

With regard to phagocytosis we shall shortly publish a paper with Dr. Stanley Warren in which are shown the following: 1. Carbon particles and bacteria to which the animal has no ferments act as innocuous substances and are phagocytosed by the polymorphonuclear neutrophiles, and these in turn by endothelial cells. 2. In an animal which is immune from the presence of a large quantity of ferment the bacteria are very rapidly broken down beyond the toxic stage, and so are innocuous, and the usual sequence of phagocytosis occurs. 3. In an animal in which the ferments are unable to completely break down the bacterial protoplasm quickly enough the toxic proteolytic degradation bodies are liberated, and these act aggressively, inhibiting phagocytosis. If these toxic bodies accumulate at a sufficient rate the animal dies and the endothelial cells do not appear in the exudate. If, however, the toxic bodies do not accumulate so rapidly, the polymorphonuclear neutrophile cells, after a considerable increase in numbers, are able in time to phagocytose the bacteria, and eventually the usual sequence, though delayed, occurs.

So we would say that an animal is immune to a bacterium (1) if the bacterium is unacted on by the ferments and so remains innocuous, (2) if it is so rapidly broken up by the ferments present that its proteolytic degradation bodies are quickly reduced to non-toxic ones, and so it again becomes innocuous. And an animal is susceptible to a bacterium if the ferments can split off from the bacterium toxic substances in such amount as to inhibit phagocytosis. Thus to a given bacterium an animal may have very little ferment action, and little toxic substance will be split off to act aggressively, so that phagocytosis will occur and the animal will be unaffected. If, however, the ferment activity is greater because there is more ferment, or because there is a specific ferment, or because the bacterium is more fragile, then toxic substances will be liberated in sufficient amount to act aggressively, so that phagocytosis will not occur, the bacteria will multiply, and septicæmia will ensue (or the ferment may destroy the bacterium, but may be present in insufficient amount to degrade the protoplasm sufficiently rapidly to render it non-toxic, so that these toxic substances liberated will kill the animal). Further, if the ferment activity is still greater the bacteria will be rapidly degraded beyond the toxic stages, aggressive substances will not accumulate, phagocytosis will occur, and the animal will recover.

First, then, we will take organisms to which the ferment activity normally is very low, such, for example, as the bacillus mycoides (a soil organism superficially resembling the anthrax bacillus, but naturally incapable of growth at the body temperature and posessing flagella), the timothy grass bacillus, and the smegma bacillus. These organisms, when injected into the animal body, produce in the case of the bacillus mycoides no lesions (even when this organism is educated to grow at body temperature). In the case of the timothy grass bacillus a plastic peritonitis occurs with pseudo-tubercles, with massive doses in the guinea-pig, from which the animal recovers. The infection only proves fatal on the addition of butter, and only Rabinowitch has been able to pass the strain on subsequent inoculation; other observers repeating her work have failed. The organism produces no disease in rabbits.

A series of guinea-pigs were inoculated with 20 mgm. dry weight of these organisms. In the case of *mycoides*, after a week it was found that the intraperitoneal inoculation of an agar slope of mycoides grown at 37° C. produced death of a sensitised guinea pig in 60 hours. The *post-mortem* appearances were œdema of the abdominal wall, slightly turbid peritoneal effusion, enlargement and congestion of the spleen, liver, and kidneys, moderate distension of the lungs, engorgement of the right side and veins. The organism was recovered in pure culture from the œdema and peritoneal fluid, from the spleen, gall-bladder, urinary bladder, and heart's blood. Microscopically the organism was seen in the capillaries of the spleen and liver and was non-sporing. The post-mortem appearances were thus indistinguishable from those of anthrax.

With the timothy grass and the smegma bacilli an inoculation was made of one 24-hour glycerin agar slope intraperitoneally into each guinea-pig correspondingly sensitised one week previously. Death occurred in from ten days to a fortnight. The post-mortem appearances were emaciation and hair falling out, miliary tubercles throughout the body, some degree of plastic peritonitis in addition to the usual pseudo-tubercles that occur with the inoculation of these organisms into normal animals. The omentum was rolled up, infiltrated, and studded with tubercles. The organisms were recovered from the heart's blood in addition to other sources. The microscopical appearances were those of marked epithelioid reaction with the organisms in the lesions, and in the centre of some of the lesions typical granular necrosis. The post-mortem appearances were thus indistinguishable from those due to an intraperitoneal injection of tubercle bacilli.

Parallel to these is an experiment in which we were able to produce acute miliary tuberculosis in a rabbit with a very small quantity of human tubercle bacilli. The rabbit was inoculated with about 0·05 mgm. of human tubercle bacilli 14 days after sensitisation with 50 mgm. of killed pulverised tubercle bacilli. The rabbit died in one week. In a similar way Duval and Couret have shown that experimental leprosy lesions can only be produced in monkeys after previous inoculation with dead leprosy bacilli.

We found that the sensitive period for infection was from six to ten days after the sensitising dose. If, however, the second inoculation is given to a sensitised animal after an interval of a fortnight instead of a week the animal recovers and does not develop the disease, unless a much large second dose is given than in the above experiments. Late still the animal becomes so immune that the second dose, t produce any symptoms, has now to be so large that it is onl capable of producing delayed toxic death, the animal no living long enough to develop septicæmia. The reason fo this is that the ferment is increasing in quantity and i becoming more specialised as the length of time fro the sensitising dose increases. And only by using th methods we are just coming to can septicæmic death l produced.

Secondly, we will consider organisms to which fermen activity is relatively high, so that the guinea-pigs ar immune from this reason. Organisms of this description ar Hoffmann's bacillus, sarcina, proteus Zenkeri, staphyl coccus pyogenes aureus, streptococcus erysipelatis, an cyanogenus. We found that in trying to produce lesion with these organisms by the previous method w were unsuccessful, and in most of them the larg initial doses of the bacilli, 10–20 mgm. dry weight produced death from toxæmia, with occasional termina coli, &c., infections. From this we concluded that th available ferment present was capable of rendering non toxic relatively large quantities of bacteria. Such being th case, we thought that if by some means we could (1) prevent the ferment getting rapidly at the bacterium, or (2) delay ferment action, we should be able to produce septicæmia with these organisms; for we should prevent the rapid breaking down of the bacteria, and so allow aggressive substances to be formed. The bacteria would then be able to multiply *in situ* until the available ferment was so reduced that the organisms would be able to pass into and multiply in the blood stream. To obtain this result we injected the bacteria in 15 and 30 per cent. gelatin, and 2, 3, and 5 per cent. saline. The gelatin was used with the idea of delaying the access of the ferment to the bacteria, and of keeping the degradation products formed in their immediate vicinity and so produce around them a state of ferment equilibrium. The bacteria, then, as a result of this could multiply. The viscosity of the gelatin would further tend to delay the advent of the phagocytes. The gelatin might be thought to be able to produce toxic results by itself, which we found not to occur, or in adjuvanting the toxic substances formed from the bacteria by degradation bodies from the gelatin itself. That this latter apparently is not the case can be seen from our experiments in which egg sensitised guinea-pigs, receiving a second dose of egg albumin, so as to produce a great fall of temperature lasting for hours, were not susceptible to several slopes of staphylococcus inoculated simultaneously, though degradation bodies from the egg must have been present.

The hypertonic saline, as has been shown by Friedberger and his co-workers, inhibits ferment action, and we conceived that by injecting hypertonic saline into the peritoneal cavity the ferment action would be delayed until the necessary dilution of the saline had occurred by osmosis. We will discuss the effect of hypertonic saline on the bacteria later. Working by these methods we were able to produce fatal septicæmia with all these organisms, but the amount of bacterial substance required was very different with the different bacteria. The less primarily toxic the bacterium was, the more was required to produce septicæmic death.

Except in so far as the gelatin method can be used for demonstrating that where large amounts of ferment are presumably present, the amounts of bacterial substance required to produce septicæmic death are correspondingly large, in the light of further work we do not consider the gelatin method a good one for proving immunity due to large quantities of ferments; for we have been able to produce by this method, but not by the saline, acute septicæmic death with an unpassed mycoides (growing 37° C.). This can readily be explained. Friedberger was able to produce anaphylotoxin in the peritoneal cavity of guinea-pigs with any bacterium. We have noted that where large amounts of coagulated egg albumin are introduced into the peritoneal cavity toxic substances are formed from it, producing a fall of temperature. In the same way similar substances can be liberated from the bacillus mycoides, and in the viscid gelatin, zones of ferment equilibrium become established round the bacteria; the ferment then is incapable of destroying them, and by the time the delayed phagocytes arrive at the bacterium the aggressive substances prevent phagocytosis and the organism is able to survive.

Thus we have proved that the pathogenicity of bacteria depends upon the activity of the ferments in the animal host. If there is no, or slight, activity the organism is non-pathogenic, if there is a high degree of activity again the bacteria are non-pathogenic; and by either increasing or diminishing the ferment activity, as the case may be, the bacteria may be rendered pathogenic.

Now with regard to virulence of bacteria. This must be regarded as entirely an educative property acquired by the bacterium. Gal showed that bacteria could be rendered virulent by cultivation in the presence of an enzyme, such as the enzy[illegible] t bacteria [illegible] virulent,

We have shown (1) that bacteria which are primarily non-pathogenic can, after passage through a sensitised animal, become so altered that they now produce disease in a normal animal—that is to say, they can be acted upon by the normal ferments so readily that sufficient aggressive substances are formed; (2) that organisms which have been obtained from the blood of septicæmic animals, which are normally immune owing to the high activity of the ferment, inoculated into normal animals, will produce disease and death; and (3) that some organisms when they become virulent can develop a capsule. With regard to the first of these points we have been able to produce disease followed by death in normal animals after inoculating with passed bacillus mycoides, timothy grass bacillus, and smegma bacillus, not only in guinea-pigs in which the original passage was conducted, but also in rabbits and rats. In the case of the bacillus mycoides, it eventually became so virulent after several passages that one-twentieth of a 24-hours agar slope killed a normal guinea-pig weighing 300 grm. in about 36 hours. One-twentieth of an agar slope killed a rat in 24 hours, and half an agar slope killed a rabbit in 24 hours. Finally, 18 guinea-pigs which had been placed in cages in which other guinea-pigs had died from the disease, all died as the result of intestinal infection. It is interesting to note that one guinea-pig which was pregnant was found to have the bacillus mycoides in pure culture in the amniotic fluid. With regard to the timothy grass and smegma infections, the bacteria when isolated or when injected in the ground-up spleen produced in normal guinea-pigs death with [illegible] the lymphatic [illegible]. The organism [illegible] come so virulent [illegible]

The organisms when inoculated intraperitoneally into a rabbit in small quantity produce death in a week with general miliary tuberculosis, slight fibrinous peritonitis, and enlarged glands showing miliary tubercles in the chest. This is particularly important because lesions are not produced in the rabbit by the unpassed bacteria.

With regard to the second group of organisms, these, when passed, produce septicæmia with very small quantities without the aid of gelatin or hypertonic saline. It was found that the bacillus mycoides which ordinarily has flagella and no capsule in the animal body develops a capsule and loses its flagella when it becomes virulent.

We will first discuss the composition and function of the capsule. We conceive that the capsule is composed of extruded bacterial cytoplasm, which is extruded for the purpose of engaging the ferments and preventing them from reaching the bacterium itself, and causing its death and destruction. It appears to us that the mechanism is to produce a state of ferment equilibrium around the bacterium, so that the bacterium is shielded from the further action of the ferment and is able to grow and multiply. Whether this is successful or not depends upon the relative amount of bacterial protoplasm and ferment activity. We are aided in this conception by the action of hypertonic saline, noted in our experiments. The hypertonic saline in addition to hindering the action of the ferments also appears to have an influence on the bacterium. The bacterium being in a hypertonic solution is subject to osmosis, the result of which is that diffusion of the bacterial cytoplasm occurs, thus forming a capsule in which the same condition of ferment equilibrium can be maintained in the presence of the weakly acting ferments.

In the case of the gelatin similar zones of equilibrium are maintained around the bacteria in the gelatin. The gelatin prevents rapid removal of the degradation bodies produced around the bacteria. It is conceivable also that the bacteria exude a little protoplasm into the surrounding medium which may be more soluble than the capsules ordinarily demonstrable. This is kept in position by the gelatin, so that the necessary equilibrium zone can be maintained. This is seen in the case of our experiments with the proteus Zenkeri, where an unpassed strain was injected in gelatin and in 5 per cent. saline. Seven agar slopes injected in 5 per cent. saline produced no result beyond a transitory fall of temperature, but four agar slopes in gelatin produced toxic death and eight slopes produced septicæmia. The difference in the two cases would appear to be due to the gelatin temporarily acting as a containing capsule preventing the removal of the aggressive substances.

We would conceive that exotoxin is really this capsule formation in an exaggerated degree, but differs in that the bacterium diffuses its protoplasm into the surrounding medium instead of retaining it in its immediate vicinity. And we regard exotoxin as soluble bacterial protoplasm which only becomes toxic on contact with ferment. The reason why we are led to conclude this is that with bacillus diphtheriæ and bacillus Hoffmann a septicæmia has never been produced. This appears to us to be due to the fact that zones of ferment equilibrium do not occur intimately around the bacterium, and so the ferment, which is apparently of high activity, is able to penetrate and kill the bacteria, the animal dying from toxæmia. The proof of the high ferment activity is that the guinea-pig can withstand large doses of these organisms if inoculated in the ordinary way, and that the animal does not take the disease after sensitisation. Now we have been able to obtain a Hoffmann and diphtheria septicæmic death by means of the gelatin and saline methods.

From this we conclude that by the gelatin method we were able to keep the exuded bacterial protoplasm in intimate contact with the bacterium, so that a zone of ferment equilibrium could be established round the bacterium, forming a protective sheath against the further action of the ferment. In the case of the saline, the inhibition of the ferment action and the exudation of the greater amount and the lessened tendency to diffusion of the bacterial protoplasm will bring about the same result.

That these animals die from proteolytic degradation body poisoning can be demonstrated by the fact that the inoculation of their blood intravenously into a normal guinea-pig produces acute toxic death (acute anaphylaxis). This brings the diphtheria bacillus into line with the other bacteria.

And it shows that death from bacteria possessing an exotoxin or not is always due to the same cause—i.e., proteolytic degradation body poisoning.

In order to further this view several points require explanation. How does toxin become toxoid? Toxins may be converted into toxoids by heat, by standing, by sunlight, and by drugs such as iodine. With regard to heat, if exotoxin is bacterial substance it will contain the autolytic ferment of the bacterium. Now, on moderate warmth or standing this ferment starts degrading the bacterial protoplasm, and after a time no further degradation can occur (unless the end-bodies are removed) owing to ferment equilibrium, so that at any time there will be present (1) unaltered bacterial protoplasm, which on inoculation can be converted into toxic early degradation bodies; (2) early degradation bodies, which on further action are rendered non-toxic; and (3) non-toxic end-bodies.

The much smaller amount of unaltered protoplasm is more rapidly attacked by the ferment present in the animal, so that the toxic bodies only tend to be present at any time in small amount, producing local changes at the seat of inoculation and no general poisoning. On this assumption we can also explain how it is that a toxoid can act as an antigen. Again, this explains why the fixation of complement occurs when toxin and antitoxin are added together, for we must consider the antitoxin as a co-enzyme or amboceptor.

Then, with regard to the difference between the L 0 and the L + dose, on the principle on which these are worked out, no account is taken of the normal active ferment present in the guinea-pig.

With regard to chemicals such as iodine converting the toxin into toxoid, we have the observations of Friedberger and Schittenhelm that iodised albumin can act as an absolutely foreign proteid to the homologous animal, so that iodine acting on bacterial protoplasm may so alter it that the ferments which could easily attack the ordinary toxin can now only very slowly act on the iodised "toxin." But as we know, iodised toxoid can produce antitoxin, that is, a ferment against the unaltered toxin; this is parallel to the observation of Schittenhelm that guinea-pigs sensitised against iodised egg albumin can react not only to that but to plain egg albumin. This means that the newly evolved ferment can also degrade the non-iodised homologous proteid.

Though we have discussed so far pathogenicity and virulence separately, yet we have come to the conclusion that they must be considered together. Thus an organism by passage may become so altered that it is able to infect and multiply in an animal in which there is no specific ferment. The mycoides could only become pathogenic in the first instance on inoculation into a sensitised animal—that is, an animal that has acquired a certain amount of specific ferment. After passage this organism is capable of producing disease in a normal animal—that is, an animal which only contains panenzyme. Hence we must conclude that the bacterium has become so altered that it can be attacked by the panenzyme at such a rate that sufficient aggressive substances are formed to prevent phagocytosis, and developed the property of extruding a capsule to form a protective zone in which ferment equilibrium occurs to prevent the enzyme from penetrating and destroying it. Thus we see that a bacterium which is virulent may also be pathogenic. The passed smegma and phlei are similar.

Now we must consider the bacteria which are not under ordinary circumstances pathogenic, and which do not become so when the ferment is raised against them by the production of specific antibodies. The first point we must discuss is the activity of the ferment. We have come to the conclusion that septicæmia is not produced by a process of *general ferment* equilibrium in the whole animal body; but that septicæmia occurs if the relation between the quantity of bacterial protoplasm and the ferment activity is such that aggressive substances are formed from the bacterial protoplasm by the ferment in sufficient amount and remain as such long enough to inhibit phagocytosis.

Now first of all we can compare *in vivo* experiments with experiments carried out in the test-tube. From theoretical considerations the quantity of ferment only influences the rate of degradation, not the amount. So that *in vitro*, no matter how much ferment is present, ferment equilibrium eventually takes place and the same amount of the undegraded material remains in the two cases. This would mean unaltered bacterial protoplasm. We know from experiments *in vitro* that under these conditions after ferment equilibrium has occurred the bacteria start to multiply again. Now, taking two guinea-pigs with the same quantity of ferment, if in one the ferment activity is unaffected and in the other the ferment activity is damped, and into each the same amount of living bacterial protoplasm is inoculated, ferment equilibrium should occur in both, and septicæmia, if it occurs in one should occur in the other, but at different times. But we find that where the ferment has been damped septicæmia occurs, and not in the other. Hence we must conclude that septicæmia is not produced by general ferment equilibrium in the animal body alone. Taking account also of rate of removal of end bodies in both cases, these are being gradually removed, in the one case more rapidly than the other; so that in both cases, theoretically, if the amount of ferment is sufficient, the primary substance should be completely broken down. Hence we must conclude that the occurrence of a septicæmia depends upon the presence at any given time and the maintenance of early degradation products sufficient to prevent phagocytosis. Where the ferment activity is great, the accumulation of the aggressive early degradation bodies is temporary, so that the inhibition of phagocytosis is only temporary, and this ceases directly the bodies are further degraded.

Finally there remains for discussion the fact that these organisms, which by our methods have produced septicæmia, are now able when directly inoculated into a normal animal, and in much smaller doses, to produce septicæmia. The fact that they can do so is a great argument against fermentative equilibrium being the sole cause of septicæmia.

Taking two normal animals and inoculating the same quantity of passed and unpassed bacteria, in the former septicæmia occurs, in the latter nothing. Here the factors are the same: the same activity, the same weight of bacterial protoplasm; hence if septicæmia were solely due to general ferment equilibrium septicæmia should occur in both. Hence we conclude that the difference is due to the retention around the passed bacterium of bacterial protoplasm in various stages of degradation, forming on the one hand an aggressive shield against the phagocyte, and on the other against the ferment, so that the bacterium can multiply Here again we believe that a bacterium which is virulent i so in virtue of its being able to exude some of its cytoplasm around itself and not into the surrounding medium, and w should expect that on these lines a diphtheria bacillu which became virulent would not produce soluble exotoxin but keep its halo of bacterial substance around itself. Tha this is probably so is brought out by the well known observation that a very virulent diphtheria bacillus produces very little exotoxin.

Conclusions.

1. Ferments form an important normal mechanism of defence against bacterial invasion. The ferments performing this important function are: (*a*) the normal panenzyme, (*b*) the slightly differentiated specific enzyme, (*c*) the thermolabile specific coenzyme or amboceptor, and (*d*) the thermostable specific coenzyme or amboceptor. These last two adjuvant and accelerate the action of the ordinary enzyme. The action of the ferment is to bring about proteolytic digestion of the bacteria.

2. Exotoxins and endotoxins are bacterial protoplasm and are not primarily toxic *per se*, but only become so when acted upon by the ferments.

3. The action of the ferments on the bacterial protoplasm is to produce toxic early proteolytic digestion bodies. These bodies, besides being toxic to the animal, are also aggressive in the sense of Bail—i.e., are anti-phagocytic.

4. The action of this toxic substance, besides being aggressive, is to produce (*a*) in large amounts, death; (*b*) in lesser amounts, fall of temperature; and (*c*) in small amounts, fever. This substance is the cause of death in all bacterial infections.

5. The virulence of a bacterium is dependent upon the power of exuding around itself a zone of its cytoplasm, which remains in position and acts as a protective shield. The production of a zone of ferment equilibrium in this shield protects the bacterium itself from the penetration of the ferment. The shield thus acted upon is also aggressive to phagocytosis.

6. Pathogenicity is due to (*a*) the virulence of the bacterium, and (*b*) the relative activity of the ferment to the bacterium. Thus we should say that immunity is due to ferment action and phagocytosis—i.e., it is cellulo-humoral.

THE JUGULAR PULSE

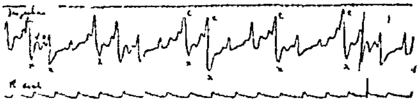
By H WALTER VERDON, F R C S ENG

OBSERVATIONS made below on the deflections of the jugular curve may prove of interest to readers who like myself, are following Dr James Mackenzie's methods of clinical cardiography

The c wave —The absence of a dicrotic appendage from the c wave is proof that this wave is not the product of an ordinary arterial impression On anatomical grounds alone it cannot be said to take its origin from carotid pulsation because, below the sinus vein and carotid artery do not lie in contact but are separated from one another by an interspace giving room for the lodgment of the vagus nerve The wave might be regarded as resulting from pulsation of the subclavian or innominate arteries, but here again the absence of dicrotic appendage creates difficulty On the other hand, relationship between venous and arterial columns is intimate in the neighbourhood of the aortic arch The vena cava superior, conducting blood to the auricle from its tributaries in the neck lies in touch with the ascending limb of the aorta and embraces it on its posterior and right lateral aspects During the sphygmic period, elongation of the arterial arch takes place, and elongation is followed by recoil This lurch of the aorta which is additional to pulsatory phenomena, common to all arteries cannot fail to be instrumental in transmitting an impulse to the venous column, and the resulting wave must necessarily consist of simple positive and negative curves unattended by any dicrotic encumbrance It is therefore suggested that the aorta is the source of origin of the c wave (See Fig 1)

X and y depressions, and v, a, and c eminences —Depression x occupies a prominent place in the jugular curve It extends to a lower plane in the normal tracing than that attained by any other deflection, a fact indicating that here auricular pressure reaches its extreme limit of minus quantity It is a landmark separating the territory of a cyclic period from that which precedes and that which follows it It records the *fraction of time when a period is closing* with the end of ventricular systole and when another period is *opening with the beginning* of ventricular diastole, consequently an alternating series of x depressions and triple waves is the distinguishing feature of the jugular curve (Fig 1)

FIG 1



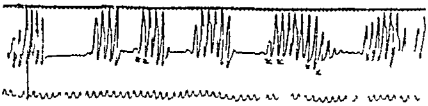
The declivity of the c wave is noticed in the above curve as descending to the fundus of the x depression unattended by a dicrotic appendage

[illegible] cyclic period of the tracing and [illegible] one x depression to the fundus [illegible] the semblance of a triple wave is in reality a simple curve deflected at its apical part by the upheaval of eminences usually differentiated by symbols v a and c In the case of normal and slow pulses this simple cyclic wave is bisected at a point lying between v and a eminences by the interpolation of the y depression But the y depression is not a constant feature When pulsation rises above the normal beat rate it appears only as *a mere indentation* of the curve, and when pulsation *still* further quickens it becomes entirely obliterated, leaving no trace of its presence behind

Fig 2 represents the curve of a very rapid pulse from which the y depression is absent Figs 3 4, and 5 show the evolution of the y depression as the pulse slows down In Fig 3 it appears as a mere indentation interposed between the eminences v and a at the apical part of the cyclic wave In Fig 4 representing a pulse of normal rate this depression splits the cyclic wave except at the basal part, forming two distinct undulations v and a Fig 5 represents a pulse of 35 beats a minute *The y depression completely bisects* the cyclic wave and extends even below the plane of the x depressions which fix the limits of the cyclic period

The y depression cannot, therefore be regarded as representing a process in the cardiac syndrome essential to the maintenance of the circulation It is caused by a momentary fall in intracardiac pressure when the muscle forming the wall of the right ventricle becomes attenuated by relaxation and hence more open to the influence of aspiratory energy lodged in the media of the heart's environment

FIG 2

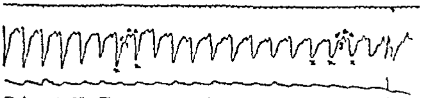


Pulse-rate 210 [illegible]

diastole the downstroke with that of ventricular systole

Eminences v, a, and c also represent processes in the cardiac syndrome which are not essential factors in the upkeep of the circulation V appearing at an early stage of diastole is formed by the recoil of the a v septum a by auricular systole and c by an impulse communicated to the venous column from the aorta

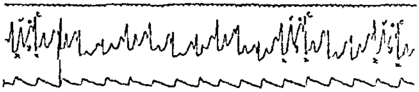
FIG 3



Pulse rate 85 The upper curve is jugular Symbols x x mark the limitations of the cyclic wave Depression y appears as a notch between the eminences v and a

The solitary jugular cyclic wave —Having now given consideration to the y depression and to the upheaval of the v, a, and c eminences which in turn deflect the curve of the solitary wave from its simple course, we must now enter upon a survey of the processes determining the rise and fall of the solitary wave itself These processes it will be observed constitute the essential forces of the circulation

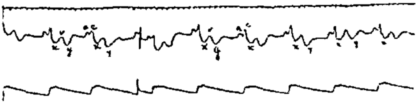
FIG 4



Pulse-rate 66 The upper curve is jugular Symbols x x mark the limitations of the cyclic wave Depression y splits the cyclic wave into two parts except at its basal zone

The pericardial sac consists of a tough, inelastic, fibrous membrane attached below to the aponeurosis of the diaphragm, above to the roots of the great vessels entering and leaving the heart, and in front to the upper and lower ends of the sternum It serves the purpose of preventing undue expansion of the walls of the cardiac cavities under the aspiratory influence of intrathoracic negative pressure which is never less *in quantity* than *minus* 8 mm Hg and sometimes attains a degree of elevation represented by minus 30 or 40 mm Hg

FIG 5



Pulse-rate 35 The upper curve is jugular Symbols x x [illegible] y depression [illegible] cyclic wave

During systole the cone of the heart descends drawing down with it the floor of the auricles and occupies a restricted space at the fundus of the pericardial sac. The venous column engaging the right auricle and filling the great veins entering this cavity also falls to a lower plane than that previously occupied by it, and is thus more fully exposed to the influence of a minus pressure environment. Thus the declivity of the solitary jugular cyclic wave runs synchronously with ventricular systole.

At the end of systole diastole begins. The cone of the heart expands, pushing backwards the *a.-v.* septum and occupying the pericardial sac almost to its full capacity. Since the tricuspid valves open towards the ventricle, they float with the blood stream and oppose no obstacle to its entrance; moreover, the opening of these valves causes no deviation in intracardiac pressure. Consequently, during the period of diastole auricle and ventricle constitute a single chamber in which pressures become instantly equalised. The inflowing venous stream, which gradually fills this single cardiac chamber and afterwards backs itself up in the tributory veins, neutralises intracardiac minus pressure, converting it to a positive quantity, and thus causes a steady rise in venous pressure.

In the jugular curve, when the pulse-rate is above 80, very little is noticed of the *y* depression, because the volume of the incoming stream is more than sufficient to keep pace with the relaxation of the ventricular wall, and because ventricular systole begins while auricular pressure is still rising; consequently the acclivity of the solitary jugular curve runs synchronously with ventricular diastole.

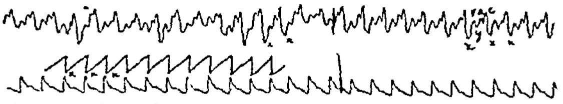
In the slow pulse, however, in which case diastole is prolonged, the wall of the ventricle becomes attenuated by extreme relaxation, and hence it is particularly open to the influence of aspiratory energy lodged in the media of the heart's environment. As a result minus pressure asserts itself in the auriculo-ventricular cavity, and is recorded by a negative deflection of the jugular curve recognised in depression *y*.

If deflections which do not represent processes essential to the maintenance of the circulation be eliminated it is noticed that the positive curve of the venous pulse is coincident with the negative curve of the arterial pulse, and that the fall of the venous cyclic wave is contemporaneous with the rise of the arterial.

The jugular curve, then, consists of a sequence of cyclic waves arising from the interaction of two forces in the presence of limitations imposed by the pericardial sac. One of these forces consists of negative pressure lodged in the media of the cardiac environment, the other is exemplified by ventricular systole. These potential and these kinetic energies are engaged in filling and emptying the ventricles.

The effect upon the venous column resulting from the exercise of these energies is manifested by the appearance of a solitary wave occupying the entire cyclic period of the jugular pulse. When the jugular pulse is synchronised with the radial the trend of pressures, as indicated by the curves, is identical, except that they exist in inverse order of incidence. (Fig. 6.)

FIG. 6.



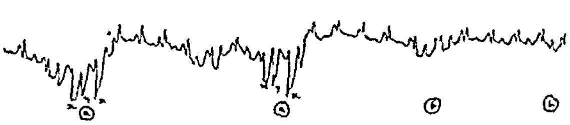
Tracing of jugular and radial pulses. Interpolated between them is a diagrammatic curve illustrating the trend of venous pressure uninfluenced by minor circulatory processes.

The respiratory curve.—The wide deflection of the jugular curve, which includes a sequence of many cyclic periods, results from the rise and fall of negative pressure in the thoracic cavity coincident with inspiration and expiration; ordinary or normal respiration produces a shallow deflection, gasping or forced respiration a deep one. Negative pressure in the thoracic chamber is maintained by sustained tension of the elastic fibre of the lungs, tautness of the bony and cartilaginous framework of the thoracic wall, tonus of inspiratory muscle, and integrity of pleural cavities.

During normal inspiration the gradient of intrathoracic negative pressure rises to minus 30 mm. Hg. During ordinary expiration and the pause succeeding it the gradient falls to minus 8 mm. Hg. During forced or gasping respiration the range of negative pressures reaches wider proportions, attaining minus 40 or 50 mm. Hg during inspiration. The greater width of range is induced almost solely by depression of the aponeurosis of the diaphragm, which while normal respiration is continued maintains a stationary plane.

Depression of the aponeurosis of the diaphragm has a particular effect on the jugular curve, as observed in Fig. 7.

FIG. 7.



The inspiratory deflections of [illegible]
by deep *x* and *y* depressions [illegible]
aponeurosis of the diaphrag[illegible]
is thoracic, and the aponeurosis remains on the same plane
during inspiration and expiration.]

With the descending aponeurosis, the pericardial sac is drawn down, and together with this structure the heart and superior cava. As a result of the fall of the pericardial sac to a lower plane, an extended area of the auricular and venous walls and the contained blood column are exposed to the influence of intrathoracic and intrapericardial negative pressures, and the effect of these influences is registered in the deep deflections of the jugular respiratory curve. These deflections are made remarkable by the width and depth of the *x* and *y* depressions.

A CASE OF HAIR CAST OF THE STOMACH; GASTROTOMY; RECOVERY.

BY L. STOREY, M.B., CH.B. GLASG., M.R.C.S. ENG., L.R.C.P. LOND.,

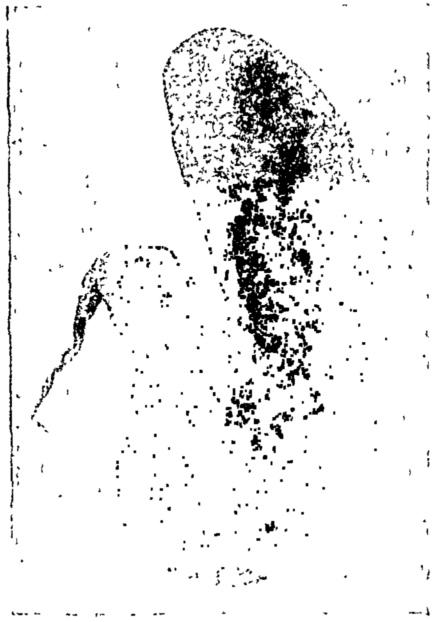
LATE HOUSE SURGEON TO THE DEWSBURY GENERAL INFIRMARY.

HAIR casts of the stomach are of such comparative rarity that the following case seems worthy of being placed on record.

The patient, a girl aged 17, was admitted to the General Infirmary, Dewsbury, on June 29th, 1910, complaining of vomiting, loss of flesh, and general weakness. Small and unhealthy in appearance at birth, the first few months of her life were a source of great anxiety to her parents. Improvement, however, set in: at 3 years of age she was able to walk and at 5 years to go to school. At the later age a small "lump" was noticed in her abdomen. The medical man who was consulted gave it as his opinion that the child was suffering from "consumption of the bowels." This swelling slowly increased in size, and her general condition remained unsatisfactory throughout her school days—i.e., from 5 to 13—and during that time she was under medical care on six or seven occasions. During the next four years the local swelling slowly increased in size, whilst the general condition deteriorated, and at Easter, 1910, the vomiting was so persistent that she had to give up work. Swelling of the feet in the evenings, breathlessness and palpitation on exertion, pains in and swelling of the knee-joints, with an evening temperature of 104° F. necessitated removal to hospital. Save for the fact that when 2 years of age it was noticed that the left side of the head was "quite bald" and that small masses of hair were being passed by the bowel, the previous health was uninteresting. There was no history of insanity in the family, and the girl herself was considered to be "the life of the home."

On admission the patient was apparently anæmic and markedly emaciated. Her height was 4 ft. 2 in. and weight 3 st. 11½ lb. The hair was abundant, with plaits 14 in. in length, somewhat thin in the temporal regions, and of a mid-brown colour. Evidences of rickets were present. The temperature was normal. Save for a prolongation of the first sound at the apex, unconducted and unaccompanied by accentuation of the second pulmonic, the heart was normal. Examinations of the lungs, urine, and blood were negative. The abdomen was distended generally. In spite of this, however, a distinct swelling was visible and palpable in the lower epigastric and upper umbilical regions. The swelling was hard and immobile. There was no free fluid in the peritoneal cavity. On July 28th, 1910, laparotomy was performed and a mass of hair was removed from the stomach. The patient made an uninterrupted recovery.

The mass of hair was hard and an exact cast of the stomach (see illustration) It weighed 2¼ lb. In length it measured 10½ in., the great curvature 20 in., and the lesser 10½ in. Though not unique in dimensions, it is in my opinion the truest cast recorded.



Hair cast of the stomach weighing 2¼ lb.

According to Butterworth's[1] comprehensive article on this subject there have been 42 such cases reported, 39 of the series occurring in females. Two other cases were also recorded about the same time, one by Newbolt and Jones[2] and the other by Still.[3] The youngest case was that of a girl aged 8 years, and the oldest an insane man aged 43. In 75 per cent. of the cases the habit commences during the first few years of life. One would imagine insanity to be a more frequent cause. In only four of the cases, however, has it existed. The majority of hair balls are of small size. The smallest, recorded by Ilderton,[4] weighed 2¼ oz., whilst the largest on record, that of Mermet d'Hauteville,[5] weighed 6 lb.

I am indebted to the members of the honorary medical staff for permission to report this case.

Huyton, Liverpool.

ROYAL SOCIETY OF MEDICINE.

SURGICAL SECTION.

Actinomycosis.—Streptothrix Infections.

A MEETING of this section was held on Jan. 14th, Mr. G. H. MAKINS, the President, being in the chair.

Mr. A. G. HAYNES LOVELL read a paper on Actinomycosis, with special reference to involvement of bone, and gave an account of a case in which the inferior maxilla was primarily involved. It was that of a man aged 23. On July 20th, 1911, pain began without cause around the left lower canine tooth, then pain in the first molar. The latter was extracted though apparently healthy. Then pain started in the second bicuspid in which thermal sensation was much impaired. This was extracted, but showed no sign of disease. On August 1st external jaw swelling appeared and pain still continued. On the 12th his temperature was 99° F. A mass of the size of a walnut was now present in connexion with the lower jaw. No sinus occurred nor sign of disease in the mouth. A skiagram by Sir James Mackenzie Davidson showed rarefaction and suggested an abscess at the root of the first bicuspid. There was no sign of new bone formation or periostitis. Three teeth in front of those extracted were loose and their sensation was diminished. A few days later an incision let out a little pus. A film of this showed no organisms, but a culture after eight days grew a streptothrix—Gram-positive and acid-fast. The sulphur granules were now found in the scanty pus. On August 24th pot. iod. gr. xv. t.d.s. was started. On Sept. 1st an autogenous vaccine was used and repeated at ten-day intervals. On the 5th the bone was scraped subperiosteally, and the pot. iod. increased to gr. xxx. t.d.s. On Dec. 9th the swelling was very much smaller, but the sinus persisted A skiagram showed less rarefaction, but still an abscess cavity. On Feb. 16th, 1912, the difference between the two sides was only just perceptible, and treatment was stopped. The patient was still quite well. In remarking on the pathology of the condition, Mr. Lovell said that bone was usually involved by extension from disease of adjacent soft parts. The only region where an apparently primary disease of bone occurred in man was in the jaws. Here it was probably due to infection through sockets of carious teeth. Primary bone lesions had never been produced experimentally. Two cases of isolated foci in bones were reported—one in the lower end of the femur and one in the upper end of the tibia. Poncet gave the best description of bone involvement. There might be: (1) Periostitis due to adjacent disease of soft parts; (2) peripheral rarefaction (rare); (3) a central perforating type (case here described), the commoner type in man; (4) a central neoplastic type, common in cattle. The central perforating type might progress to parchment crackling and spontaneous fracture, but usually the bone was perforated in several places and sinuses resulted. Sequestra of any size rarely or never occurred. Toothache was an early symptom. Subsequently teeth became loose and their sensation impaired. There was little or no true bony thickening in these cases.

Mr. T. H. KELLOCK read a paper on Some Clinical Features of Actinomycosis. He stated that the occurrence of this disease seemed to be more and more frequent, and it had always to be borne in mind when discussing diagnosis. From its prevalence in people of all classes of society, of all ages, and in persons of various occupations, it would seem that the organism in some of its varieties had ceased to exist, as was formerly believed, solely on grass, hay, or straw, but had become almost ubiquitous The disease was met with under two very different conditions: the simple or clean, and when septic infection had been superadded; and it seemed difficult to demonstrate the organism in the presence of the latter. This possibly explained the difficulty of microscopical or bacteriological confirmation in many cases.

[3] [illegible]

[4] [illegible]

[5] Journal de [illegible] ne, Paris, 1813, vol. xlviii.

Probably every case was infected through the alimentary or respiratory tracts, but it might be carried by the bloodstream to organs that did not communicate directly with these tracts. Once inside the cavities of the body the organism seemed to have a peculiar tendency to insinuate itself into ducts that opened on the surface and infect thus the salivary glands, liver, and vermiform appendix. His experience of the mode of spread was that it rarely did so by means of the lymphatic circulation, and it was very rare to find the lymphatic glands affected. Its preference seemed to be to spread by direct continuity of tissue, and, unlike tuberculosis, to ignore anatomical boundaries and cause adhesions by invading all and every structure with which it came in contact. It had been supposed that the portal vein was the means of conveying the organism to the liver when that organ had been found infected, but it seemed more likely that the hepatic infection was an independent one direct from the duodenum. For the purposes of the paper he was relying solely on cases that had come under his own notice. When the disease attacked the lower jaw the most marked feature was its painlessness as compared with a septic infection of the same part. Often the first indication was a small, red, puckered swelling on the face, preceded possibly by slight toothache or merely a feeling of tension. The spot enlarged, was found to be adherent to bone, softened in the centre, and if incised was found to contain very little pus. If the spot was small and isolated it was seldom followed by necrosis, and would often get well without any treatment beyond incision. The upper jaw was affected only very rarely; he had seen no example of it. In three cases he had found the disease affecting the centre of the cheek. In these cases he believed the infection was through the opening of the parotid duct. Infection of the various glands the ducts of which opened into the mouth was very common; he had found it in the parotid, submaxillary, and sublingual glands. In two cases he had seen the disease in the tongue, affecting the deeper parts. There was no surface ulcer. A rather soft, circumscribed, painless swelling of somewhat rapid growth without interference with the movements of the tongue, were the chief characteristics. When it affected the tissues of the side of the neck the most noticeable features were the marked fixation it caused and the manner in which it spread backwards, sometimes to the middle of the back of the neck. When the lung was the seat of the primary infection, adhesion to the chest wall often occurred rapidly. One met with chronic abscess at almost any part of the chest wall—under the heart, in the axilla, or just under the clavicle seemed the commonest places. Many cases of the disease attacking the vermiform appendix and cæcum had been recorded. Particular features in these cases had been the large amount of infiltration with comparatively little breaking down in the clean cases, and the curious behaviour of the abscesses when such occurred, lifting up the iliac vessels and infecting the psoas muscle in one case, coming to the surface in the middle line above the umbilicus in another. In one of his cases the right kidney was the part affected. The kidney was removed, under the impression that it was tuberculous, from a young woman, who besides a kidney tumour had pyuria and pyrexia. After prolonged treatment with large doses of iodide of potassium she got well, and remained so until lost sight of three or four years later. In all these cases the diagnosis was confirmed by bacteriological examination. The affections for which he had mistaken this disease, and known it mistaken by others, had been streptococcal infections in cases of the lower jaw and salivary glands; tuberculosis, sarcoma, carcinoma, gumma, and in one case for salivary calculus. To sum up, the chief clinical features were: its existence under two conditions—the clean and the septic; its comparative painlessness; the rather curious linear puckering which it caused in the skin; the way in which it infiltrated all the surrounding structures disregarding anatomical boundaries and causing adhesions; its disposition to enter ducts opening on to a mucous surface; the very little pus that was evacuated even when what appeared to be a collection of some size was opened; the rapid improvement after scraping and the administration of sufficiently large doses of iodide of potassium; and, lastly, the remarkably little deformity or disfigurement that resulted after treatment had succeeded in eradicating it.

Mr. A. G. R. FOULERTON read a paper on Some Points in the Pathology and Diagnosis of Streptothrix Infections.

SECTION OF LARYNGOLOGY.

Exhibition of Cases and Specimens.

A MEETING of this section was held on Jan. 10th, Mr. HERBERT TILLEY, the President, being in the chair.

The PRESIDENT exhibited the Chart of a patient, aged 10, with a continuous evening temperature of 100° F. for 14 days, with slight tonsillitis and enlarged glands, which had subsided. A swab tonsillar culture revealed streptococcus longus culture with staphylococci. Dr. Eyre also isolated a similar streptococcus from a bladder specimen. The opsonic index was 0·72 when an autogenous vaccine from the tonsil was injected. This was followed by a reaction. Ten c.c. of polyvalent antistreptococcal serum was injected (Lister Institute), and next day 1·25 millions of autogenous bladder streptococci. The temperature, which had mounted to 103°, subsided before the third injection of vaccine prepared from the bladder streptococci had been used. The marked improvement to the last vaccine was the feature of the case.—Mr. P. R. W. DE SANTI suggested the symptoms were due to a general streptococcal infection.—Mr. F. J. STEWARD related similar cases with recurrence of fever.—Dr. W. JOBSON HORNE did not attribute benefit to the vaccine.

The PRESIDENT also presented a case of application of Galvanic Puncture to a Tuberculous Ulcer of the Cord by the direct method under cocaine, the condition now being healed. Evidence of lung trouble with tubercle bacilli in the sputum was adduced. A case of Granular Congestion of the Left Cord, the result of an ulcer which had healed under potassium iodide, was also exhibited by the President.

Mr. C. I. GRAHAM presented a case of Cyst of the Pituitary Fossa, for which operation by the nasal route was discussed. The patient was admitted under Dr. Wilfred Harris with failing sight, temporal headaches, drowsiness, slow mental reaction, and incontinence of urine for several months. A skiagram showed the pituitary fossa to be flattened out and enlarged. Under intravenous administration of ether, an incision was made in the middle line from the tip of the nose into the lip, splitting the columella; the greater part of the septum was removed. The mucous membrane over the sphenoid was raised, and then the anterior wall and intersinous septum were removed till the pituitary fossa was opened (Cushing's method). Two drachms of fluid escaped. During the first 24 hours there were thirst and polyuria. The patient was now up and well, except as regarded his sight, which was improving.—Dr. G. WILLIAM HILL pointed out that in Cushing's operation the upper lip was turned up, and referred to the advantage in the use of Killian's long speculum.—Mr. STEWARD requested that full notes be inserted in the "Proceedings," as this was the first case dealt with by this procedure in England.—Dr. DAN MCKENZIE intimated that Hirsch, of Vienna, had found that the advantage of this route was the diminished danger from sepsis.

Mr. L. COLLEDGE exhibited two cases of Laryngeal Paralysis due to central lesions in the vagus area, probably tuberculous in nature.—The PRESIDENT recalled a case of syringomyelia in which somewhat similar signs were present. —Mr. F. A. ROSE related a somewhat similar case which recovered.—Dr. L. W. HEMINGTON PEGLER ascribed the lesion as due to a pachymeningitis.

Mr. G. W. BADGEROW'S case of Congenital Web of the Larynx, in which a white web was attached to the anterior two-thirds of the cord in a boy, aged six, was the subject of a prolonged discussion.—The PRESIDENT described a case in which coloboma iridis was also present.—Mr. C. A. B. HORSFORD recommended excision by the indirect method; it was well to be prepared for tracheotomy.—Dr. HILL recommended a laryngo-fissure kept open for one month, during which time a splint is inserted. A particular case of his cannot do without a tube, but can speak quite well.—Mr. A. S. HUTCHISON questioned the advantage of operation unless good articulation were obtained.—Dr. H. W. FITZGERALD POWELL considered that such cases were best left, though Lack's tubes used after a laryngotomy gave good results.—Dr. J. DUNDAS GRANT was of opinion that such a condition would call for tracheotomy during one of the exanthemata.

Dr. E. A. PETERS presented a case of Extraordinary

Mobility of the Tongue which could be passed into the postnasal fossa —Mr G W BADGEROW indicated that irritation of the pharynx was the immediate cause of the use of the tongue —Dr J DONELAN described that suicides in slave ships were caused by passing the tongue in this manner

Dr PETERS also presented a case of Multiple Papillomata of the Larynx which Dr JOBSON HORNE considered should be dealt with by the direct method, and removals, if necessary, repeated once a month —Mr STEWARD also recommended this method and considered that the difficult age was about 2 years By the age of 9 the tendency to recur had diminished —Mr C W M HOPE supported this view though the resulting œdema sometimes led to a necessity for intubation —Dr POWELL mentioned that tracheotomy alone cured some cases —Mr T A ROSE had used sulphate of magnesia without improvement —Dr HILL saw such cases every fortnight —Dr DUNDAS GRANT removed the growths as they appeared and rubbed in alcohol and salicylic acid into the base —The PRESIDENT mentioned a case of his which sprouted with papillomata even in the tracheotomy wound This patient had undergone 43 operations and was seen every two or three months

Dr HILL then took the chair

Dr PETERS showed a case of Soft Bony Growth of the Antrum in a girl aged 14 years It was opaque to transillumination and the walls except the palatal bulged slightly An artificial antrum had been scooped out of the solid mass nine months ago and the condition was stationary —Dr W H KELSON referred to similar cases in which the condition was bilateral —Mr W G HOWARTH inquired as to the translucency —Mr F H WESTMACOTT had experienced such cases which were due to a hyperplasia instead of vacuolation of the superior maxilla, he advised gouging out of all the soft material contained in the bone, and considered the prognosis in a case so treated to be good

Mr HOPE exhibited a case of Unusual Form of Syphilitic Laryngitis which had occurred during residence in Norway The uvula arytenoids and superior ventricular bands were occupied by white solid swellings The palate was not anæsthetic, but healed scars were present Wassermann s reaction was positive, and 0 6 grm of salvarsan was given with marked reaction and subsequent local improvement Another similar intravenous injection was followed by another reaction —Dr LIEVEN (Aix) considered that in t [illegible]

[illegible]

actions were dangerous and had probably caused the death of many patients In one series of early cases in which there was no glandular enlargement Wassermann s reaction became negative in 5 per cent , but this was rarely the case The relapses of secondary cases treated by the salvarsan method were uncommon , he considered that only a few of the fatal cases had been published

Dr JOBSON [illegible] with pain running up in [illegible] ath The tongue was p[illegible] ere was a fulness at the base of the tongue A course of *potassium* iodide resulted in cure of the condition which was probably due to gumma at the base of the tongue

SECTION OF OBSTETRICS AND GYNÆCOLOGY

Adenomyoma of Recto uterine and Recto vaginal Septa —The Lighting of Continental Operating Theatres —Foreign Bodies Removed from the Abdomen

A MEETING of this section was held on Jan 2nd Dr AMAND ROUTH the President being in the chair

Dr CUTHBERT LOCKYER read a paper on Adenomyoma of the Recto uterine and Recto vaginal Septa, in which he first remarked on the rarity of new growth arising in the connective tissue space intervening between the rectum on the one hand and the uterus and vagina on the other, he had been unable to find any such case recorded in the 49 volumes of Transactions of the Obstetrical Society of London He described in detail a case which had come under his own observation The patient was a sterile married woman aged 35, for the previous 12 months menstruation had been excessive , there was a good deal of pain in the rectum worse at night, and latterly the defæcation had become difficult There had been no bleeding from the bowel On examination a hard mass was felt in the posterior fornix, which was attached to the supravaginal cervix and projected into the lumen of the rectum the rectal mucous membrane covering it being intact The vaginal cervix was normal On laparotomy being performed the body of the uterus and the appendages were found to be normal there was no cellular infiltration and the growth, which was below the peritoneal reflection was firmly fixed to both rectum and uterus The ureters were first dissected out, the left one being firmly incorporated with the growth , the uterine arteries were then tied *and the parametric* tissues divided as far out as possible The bladder was next separated, and the anterior vaginal wall divided Then the rectum was divided between clamps above the growth freed as low down as possible and again divided together with the posterior vaginal wall below the growth The lower end of the rectum was closed and the upper end fixed in a separate opening in the left iliac region Suprapubic and vaginal drainage was employed The patient was making a good recovery On microscopical examination the growth was seen to consist of dense fibro muscular tissue in which were sparsely scattered simple gland tubules surrounded by cellular tissue similar to that found around the tubules in an adenomyoma of the uterus Histologically the growth was comparatively benign Dr Lockyer suggested that the growth might have originated in some vestigial remains of the Wolffian duct

An epidiascopic demonstration on the Lighting of Continental Operating Theatres was given by Dr MACNAUGHTON JONES, and short communications upon cases in which a foreign body was removed from the abdomen by laparotomy were read by Dr H RUSSELL ANDREWS and Dr C F BLACKER

ELECTRO THERAPEUTICAL SECTION

The Use of Condenser Discharges in Electrical Testing

A MEETING of this section was held on Jan 17th Dr REGINALD MORTON the President being in the chair

Dr H LEWIS JONES read a paper entitled The Use of Condenser Discharges in Electrical Testing He claimed for the condenser method advantages which were destined to render obsolete the present method of testing by induction coil and continuous current discharges The points in favour of the means now described were greater rapidity, more precision it gave greater information and was far less painful to the person tested A condenser of known capacity was charged to a constant voltage and was then discharged through a muscle The electrodes were applied to the motor points in the usual way, or, when the longitudinal reaction was being ascertained to the distal tendon The production or non production of a contraction was all that was looked for , no need for judging whether it was sluggish or not He proceeded to describe the character of the wave of discharge and said it was easy to keep the charging voltage constant as well as the resistance of the patient because for these brief discharges there was no polarisation He referred appreciatively to the work of Dubois, of Berne *If to healthy muscles a series of gradually* increasing condenser discharges were used, the contractions all appeared very much alike except that the larger capacities produced stronger muscular contractions but if the same were done to damaged muscles they did not respond to the smallest capacities but would to larger capacities Therefore the process of testing with condensers consisted in ascertaining the magnitude of the least capacity required to produce a visible contraction in a given muscle The electrical testing which had hitherto been used was based upon the interrogation of the muscular contractility by applying to it the short waves of the induction coil and the long waves of the closure of the continuous current The tester had not known the wave length of either Dr Lewis Jones recommended the use of the metronome in all kinds of electrical testing , it gave an audible signal to the operator which told him when the muscular contraction should appear A range of 12 capacities was sufficient to commence with and they were arranged in series The smallest condenser he used was 0 05 micro farad, and the voltage he had chosen was 100 though other voltages could be employed He believed it would supersede the older method of testing and would probably bring out some new points of diagnostic value not at present suspected , it might also show some discrepancies from what they regarded as the settled order of muscular excitability in disease.

Dr. E. P. **Cumberbatch** gave details of the testing of a number of cases by the new method, and bore out the points established in Dr. Lewis Jones's paper.

Dr. R. S. **Woods** (London Hospital) expressed the view that Dr. Lewis Jones's method would revolutionise muscle testing. It not only made more definite the line between normal and abnormal muscle, but made possible the division of muscles formerly classed as abnormal into a graduated series.

Dr. C. F. **Bailey** (Brighton) described the usefulness of the method to indicate the rate of recovery in his own person.

The **President** offered his congratulations to Dr. Lewis Jones for the work he had done on this important subject. In the earlier days, when testing by condenser discharges was in the air, it was so hedged about by logarithms and complex formulæ that the ordinary physician was shy of employing it; therefore the greatest credit was due to Dr. Lewis Jones for the clever way in which he had rendered it practicable. The time seemed now at hand when the degree of response of muscles could be definitely graded, perhaps numbered, to the great benefit of medicine generally. Dr. Lewis Jones's method of increasing the wave length of the discharge was particularly ingenious.

Dr. **Lewis Jones** replied, and he was heartily thanked by the section.

MEDICAL SOCIETY OF LONDON.

The Rise and Possibilities of the General Practitioner-Surgeon.—The Treatment of Recent Injuries by Massage.

A meeting of this society was held on Jan. 13th, Sir W. **Watson Cheyne**, the President, being in the chair.

Mr. T. **North** read a paper on the Rise and Possibilities of the General Practitioner-Surgeon. He said that the object of the paper was to try to show the possibilities of operative surgery in general practice. He thought that they should see in the future the rise of men in general practice willing and anxious to do more than treat indigestion and coughs, who would not send every patient who had something just outside the ordinary run of diseases to the consultant or the hospital. In operative surgery in general practice he thought there was great scope for the spread of this movement. Patients who required operative treatment might be divided into three classes. First, the rich, who could afford whatever might be necessary in treatment. They would remain as before, going to those surgeons whom they knew or had heard of as being pre-eminent in the class of operation which they might require. At the other extreme there were the very poor, who would continue to receive treatment in the future, as in the past, from the hospitals. Between these two, and merging into each, not sharply defined, was a class who could afford moderate fees, or at any rate some fee for surgical treatment, and these in most places had not been able to find anyone willing to operate for fees within their reach, or, if willing, capable of doing it. He thought that this condition of affairs would soon pass, and that they would shortly find in most districts some man or men capable and willing to operate in all cases at reasonable fees. Up to the present in most cases these patients had gone to the hospitals, generally sent by their medical attendant and paying nothing. There was less trouble in many operations in looking after the patient, less time taken up in the operation itself than in dealing with many of the diseases in general practice, and the results were vastly more interesting and led to more increase of practice. When one had got into the way of operating in private the experience gained soon made for simplification of preparation and other details. As an example he mentioned an operation he had performed recently—a subtotal hysterectomy for a fibroid weighing 4½ lb., the appendix being removed at the same time. The operation itself took 50 minutes to perform, the preparation for it, say, an hour and a half. On the day of the operation he saw the patient twice; since then once a day, omitting Sunday. The wound would be dressed in a day or two, and then the work was practically done. It was well to compare this with a difficult confinement both as regards the amount of work required and the compensation for one's efforts. The question at once arose as to what extent operative procedures should be carried—where should the line be drawn as to their magnitude? This question could only be answered by the individual who undertook them and would vary with the amount of his experience and the number he got. Many of the major operations did not require any very great manipulative skill, and for the man who had held some good resident appointments after qualification, and who had not let himself rust, he did not see why there should be any limit if one excepted the more specialised operations. With the spread of cottage hospitals throughout the country and suburbs, the work of the great town hospitals ought to be freed to a great extent from those cases which could equally well be done in these smaller institutions if not in the patients' homes. The advantages of this decentralisation of work would be numerous. In the first place it would free the larger hospitals of many operative cases, it would do away with much of the uninteresting spade work of the operative consulting surgeon, it would give the general practitioner-surgeon more material, and it would relieve to some extent the overcrowding and expense of working hospitals in towns. The advantage to the consulting surgeon would be very great, as it would leave him more time to the consideration and development of original thought and procedure, which to-day with the stress of work he had to undertake must be very difficult. Another advantage to the surgeon attached to a large hospital would be that he could become a pure consultant, brought in to advise, give his opinion as to whether an operation was necessary or desirable, stiffen the opinion of the general practitioner-surgeon who called him in, and cement the confidence of the patient and his friends. Financially, he thought the surgeon would gain, as in the class of patient he was speaking of they could not pay the surgeon's operating fee, and consultations would be more frequently sought if the patients remained under the practitioner's care. As an instance he gave an experience which occurred to him last year. He had operated upon a child for the removal of tonsils and adenoids, and a few days after the throat became diphtheritic with laryngeal obstruction, for which he advised immediate tracheotomy. The parents of the child asked for a consultant to confirm his opinion that the operation was necessary, but not to operate. The consultant did, and stood by while he (Mr. North) opened the trachea. The child recovered. This was to his mind the ideal of consulting work. When operating in private houses there were difficulties to be overcome which did not arise in a well-equipped theatre. Attention to the minutest detail was much more essential, as one could not rely on being able to find a necessary instrument in the cupboard in the next room. There were few houses where one could not get a suitable room and, with the exception of the operating table, everything one required. One must have a portable operating table. The disadvantages of the surroundings were in many cases amply compensated for by not having to move the patient, and thus doing away with the increased nervous dread and the risk of moving in perhaps a very unsuitable vehicle. This in acute abdominal cases was a matter of very considerable importance. Nursing presented no difficulties except as regards expense, and this with a little management could be reduced to a minimum. For the operator himself, in addition to the greater attention to details mentioned above, there was another point of difference to that obtaining in operating in a hospital. He had to rely on the smallest amount of assistance. This was quite an advantage to the patient, and there were few operations which could not be performed with one assistant besides the anæsthetist. As regarded the operation itself there were a few points which were of interest in respect to private work. For the man who had come straight from hospital an operation in private must seem almost an impossibility. Accustomed to seeing the pomp and circumstance of a modern well-equipped theatre, surrounded by all the surgical luxuries of the age, he must feel that these things were essential, and would scorn to see amongst other things a kitchen pot or a fish-kettle taking the place of the high pressure steriliser. They served, however, very effectually at a pinch. Another criticism he would like to make with all humility was in regard to the teaching of aseptic surgery in hospitals to the more or less exclusion of antiseptics For a beginner, at any rate, or one operating under circumstances perhaps of hurry or in surroundings which were not altogether favourable, there was a liability of having aseptic precautions break down and infection take place which would not have happened if a mixed system had been adopted Moreover, the initial expense of the equipment for aseptic work was much greater, entailing a large steriliser containers &c, as one could not depend on getting ready sterilised dressings, swabs, &c, in a hurry Although sepsis was much less likely to occur when operating in private than in hospitals (and he spoke from experience in both), he did not think that for a beginner aseptic work should be attempted The amount of irritation produced by the antiseptic was amply compensated for by the increased security The preparation of the skin by the iodine method was a great saving of trouble, and after having now used it in a very considerable number of cases he had not yet found it fail As an additional safeguard for disinfecting the operator's hands before putting on the gloves he regularly used it It did not irritate the skin and readily washed off The anæsthetic was at first a trouble, but when one had been operating for some time one found a man on whom one could rely, which freed one from need of attention to anything except the operation Open ether was the anæsthetic which he now used for all ages In abdominal work the peacefulness it gave was equal to chloroform without its risks, and it did not give rise in bloody operations like Halsted's for carcinoma of the breast, to the increased hæmorrhage which the closed method did In infants it was admirable and did away with the anxiety which one always had with chloroform One of the advantages, or at times disadvantages, the general practitioner surgeon had over the consulting surgeon was that he saw the result of his work throughout, he had the patient with him before and after, knew his history and peculiarities better than one could possibly do who saw him perhaps only at the time of the operation, and he also had the advantage of observing the after results not only of his own but other's work This was very helpful in teaching one to avoid some mistakes To give an example, he saw a patient of his operated upon at a large hospital for movable kidney by a surgeon of world wide repute In the course of the operation he exposed the last dorsal nerve, and turning to the gallery explained to the students that he always cut an inch out of it as it very often gave rise to pain later A couple of months after the operation the patient came to him (Mr North) complaining that her belly behaved in a curious way when she coughed or strained On examining her and getting her to give a series of coughs the right side of the abdomen gradually distended like a football bladder, slowly returning to normal when the coughing ceased The kidney was as loose as, or looser than, before the fixation In the realm of the special surgeon one often saw results equally illuminating The opinions expressed in this paper were based on an experience of between 700 and 800 operations performed in general practice of all kinds from abdominal sections for hysterectomy, ovariotomy colotomy, appendicectomy, salpingectomy, uterine and kidney fixations, amputations of all kinds, most of the gynæcological operations, nephrolithotomy, lithotomy, prostatectomy, adenoids and tonsils, submucous resections of the septum nasi, tracheotomy, &c It might at once be said that it was easy to do and write about these things, but what were the results? The mortality for the abdominal sections was 4-6 per cent, and for the whole series 2 per cent Of the total mortality 35 per cent was in patients of 60 or over, and 28 per cent in patients under five years The most convincing result, however, was that his surgical work had gradually and progressively increased both in quantity and quality What had been said as applying to operative surgery might equally well be extended to the other branches of surgical and medical work In conclusion, might he say that in his opinion there was great scope for any man who undertook in general practice to pass outside the ordinary trammels of custom—for one who having made up his mind clearly and definitely as to a right course of surgical treatment for his patient, fearlessly to pursue that course if he felt competent, regardless of what people might say if he had as everyone must have at times a failure

Dr J B MENNELL read a paper on the Treatment of Recent Injuries by Massage

LIVERPOOL MEDICAL INSTITUTION

Cavernous Sinus Thrombosis—Suture of Crucial Ligaments of Knee—Congenital Anomalies connected with Umbilical Structures—Annual Meeting

A MEETING of this society was held on Jan 9th, Mr ROBERT JONES the President, being in the chair

Mr C A ADAIR DIGHTON read a short paper on Cavernous Sinus Thrombosis, with a report of two cases He alluded to the anatomy of the cavernous sinuses and the chief symptoms that had been found to characterise thrombosis His first case was that of a girl, aged 13 who had had a mastoid abscess on the right side After the radical operation on the mastoid the girl did well for a week Then her temperature ran up, she had rigors with exophthalmos drooping of the eyelids with haziness of the cornea, and optic neuritis The right internal jugular vein was ligatured close to the clavicle and dissected up to the mastoid The lateral sinus was exposed, curetted, and a current of fluid passed through it Polyvalent serum was administered She made a good recovery after showing signs of septic synovitis in several joints The second case was that of a boy, aged 6 In this case the trouble arose from the nasal region, the right orbit being affected The superior bony wall of the orbit was removed, the frontal lobe elevated, the cavernous sinus curetted, and a rubber drain introduced The child died from acute meningitis

Mr R E KELLY showed a case in which he had Sutured the Crucial Ligaments of the Right Knee joint in a carter, aged 33 years, with excellent results The man had been kicked on the outer side of the knee while the joint was extended, a portion of the skin on the inner side being caught as a fold between the ends of the tibia and femur There was extreme mobility of the joint It could be dislocated backwards and replaced easily The leg was put up in a Thomas's knee splint for five days Then Mr Kelly opened the joint by a long horizontal incision The crucial ligaments and the internal lateral ligament were sutured with 30 day catgut The wound was closed and the leg kept at rest on a Thomas's splint for three months—The PRESIDENT congratulated Mr Kelly on the results and said he had seen several cases where this injury had occurred recover without operation if fixed on a splint at once—Mr W RUSHTON PARKER also thought that, though the result justified the operation in this case, in most cases immediate fixation was the most important point in treatment—Mr G C E SIMPSON related a case where he had started treatment four months after the injury, with the result that after six months of splint treatment there was still a flail joint

Mr SIMPSON read a paper on Congenital Anomalies connected with Umbilical Structures These included abnormalities due to relics of the vitelline duct, relics of the allantois, and faulty closure of the lateral folds of the embryo Three recent cases of laparotomy for congenital exomphalos were related In one case the major part of the liver was included in the sac The other two cases were successful In two cases of ectopia the trigone of the
bladder had bee portion of the
large intestine r four months
dying then from m the shock of
the operation were discussed
and a case of urachal umbilical polypus was described Cases of umbilical polypi due to abnormalities of the vitelline duct were considered Four had been treated with success The results of a Meckel's diverticulum were illustrated in various forms The paper was illustrated by slides and specimens

At the annual meeting held on Jan 16th the following office bearers and members of Council were elected Those marked with an asterisk did not hold the same office last year—President Robert Jones, Vice Presidents *Thomas Bushby, *W B Warrington, C J Macalister, and J Lloyd Roberts, Treasurer, R J Hamilton, General Secretary, *Frank Hugh Barendt, Secretary of Ordinary Meetings, Alexander Stookes, Secretary of Pathological Meetings, W Blair Bell, Librarian, *Nathan Raw, Editor of the Journal, John Hay, Council, T R Bradshaw F B Grimsdale, Edward W Hope, W S Henderson, N Percy Marsh C E Solomon *R E Harcourt, *M T Stack *A W Riddell, *D Moore Alexander, *J A Howard and *W B Bennett, Auditors W S Henderson and *A P Hope Simpson

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

An Endemic Febrile Illness.—Bone and Joint Tuberculosis.

A meeting of this society was held on Jan. 15th, Mr. J. M. Cotterill, the President, being in the chair.

Dr. Charles McNeil and Dr. J. P. McGowan communicated a paper on Endemic Febrile Illness, with Acutely Fatal Cases, occurring in a Boys' Industrial School, in which they described outbreaks of peculiar illness in an industrial school near Edinburgh that they had investigated. These had occurred over a period of ten years, and while prevailing in the colder seasons had also happened in summer. Evidence of contagion of the disease from boy to boy was wanting, and the officials of the schools had shown a complete immunity from the attacks. The illnesses assumed three clinical types: acute cases terminating fatally in a few hours, of which 20 cases were collected in all; irregular and apparently lobular pneumonia—total 51 cases; simple febrile illness—total 175 cases. The evidence that these types were variations of a single morbid entity—an irregular pneumonia—was that the three types occurred together in groups; that in their manner of onset and clinical course similar symptoms were shown; that cough and spit, though frequently absent, were present in a few cases of all three types; and that the sputum, when examined, always showed pneumococci. Post-mortem evidence, by showing either acute congestion or irregular consolidation of the lungs, confirmed this suggestion of irregular pneumonia. In explanation of the unusual prevalence and the irregular types of pneumonia in the school, the authors advanced the hypothesis that this might be due to an abnormal constitution or diathesis pre-existent in the boys. Some proof of this was found at certain of the necropsies in the enlargement of the thymus and other lymphoid tissues of the alimentary tract—the appearances of status lymphaticus. The hypothesis, therefore, was that some morbid diathesis had been present on a large scale and over a long period in the school, and that in the acutely fatal cases it corresponded to that of status lymphaticus. They did not attempt any explanation of the real nature of this morbid diathesis, nor were they clear as to what caused it. The probability lay in some defective conditions of environment, and at the school the boys, in their opinion, were unduly exposed to cold and were also overcrowded.—Dr. John Green said that he had charge of the institution when the first fatal case occurred. He noted that if the temperature of the patient went above 102° F. death invariably followed. The only means they had found of preventing the epidemic was to put the boys out under canvas. Only strong boys succumbed, and two of the strongest boys who were employed in carrying out the beds to the tents succumbed the next day. Puny boys always recovered.—Mr. Henry Wade thought that the boys died from a pneumococcus septicæmia. He had isolated such organisms from the brain, epicardium, and blood of fatal cases. He thought that the inmates of such homes resembled wild animals in the free, open life which they had led previous to their reception in the institution, and like wild animals in confinement they frequently died suddenly. He did not think there was much evidence of status lymphaticus in the cases.—Professor H. Harvey Littlejohn said that status lymphaticus was not a cause of death, but that it led to death very easily from other causes. In his own experience he often found this condition present, though it might not be possible to find the real cause of death. In infants, however, he was of opinion that status lymphaticus produced death. An enlarged thymus gland pressed on important organs, and thus the heart might be injuriously compressed. This might account for the statements which mothers frequently made as to the child turning blue in the face. Individuals with status lymphaticus always appeared well nourished, but this indicated not a real but only an apparent strength. He was of opinion that in such institutions generally they did not find that robust state of health which they might expect to be present in the inmates.

Dr. Alexander Goodall and Dr. R. W. Johnstone also took part in the discussion.—Dr. McNeil, in his reply, stated that there were about 300 of such industrial schools throughout the country, all maintaining the same class of boys, yet only a few of such schools showed these epidemics.

Mr. John Fraser read a paper on Bone and Joint Tuberculosis, in which he summarised his remarks under (*a*) etiology, (*b*) pathology, and (*c*) treatment. (*a*) *Etiology:* The essential etiological factor, he said, was the lodgment of the tubercle bacillus, but this was intimately related with two secondary considerations of even greater importance, (1) the type of the causative bacillus; and (2) the route by which it reached its site of development. 1. As to the type of bacillus, from the point of view of pathology, and more especially from the clinical aspect, the human and bovine types of tubercle bacilli claimed attention. The routes by which the bovine bacillus attacked the human body might be limited to one, the alimentary tract. This tract was infected by ingestion of infected material, chiefly milk; therefore the question of milk infection was at the bottom of the seeking after knowledge in regard to this type of bacillus in bone and joint tubercle. Five possible tests to differentiate between human and bovine bacilli were recognised. (*a*) The rapidity of growth upon mediums, Tubercle bacilli might be grown upon various media, a very suitable one being inspissated egg. In comparing cultures of the human and bovine organisms the human bacillus would have grown at the end of a common period more luxuriantly and profusely than the bovine. But this was by no means an absolute test. In many cases the organism grew neither profusely nor scantily. (*b*) The second test was based upon another peculiarity in growth. Glycerine had a depressing effect upon the growth of the bovine bacillus, but stimulated the development of the human bacillus. If a doubtful bacillus was grown on a medium of egg and glycerine, a profuse growth meant the human type, a scanty growth or none the bovine. But this test also was by no means absolute, for a similar reason as before. (*c*) The morphological character of groups of tubercle bacilli, long bacilli being considered to be human, short squat bacilli bovine. For all practical purposes this test was useless, but to one morphological characteristic some degree of distinctive quality must be attributed—viz., the characteristic of nodule staining. Certain bacilli when stained with a modification of Erain's *stain* (Meule's method) showed dark nodules resembling spores. Such bacilli were almost certainly human, though all bacilli which did not show them were not necessarily bovine. (*d*) In Theobald Smith's test a medium was used consisting of bouillon and glycerine of a known slight acidity, upon which the bacilli were grown. During growth certain changes became apparent in the acidity of the medium. Progressive increase in acidity was taken to indicate the human type; diminished acidity, or even alkalinity, the bovine. (*e*) *The inoculation test* was one about which there was no doubt; its execution was easy; the result absolute. It depended on the susceptibility of the bovine species to infection with the bovine bacillus. For economic reasons rabbits were more suitable than calves. A full-grown rabbit was injected intravenously with a small known quantity (0·01 mgm.) of tubercle bacilli. The rabbit might show no ill effects, its weight might increase or remain constant, and if it was killed, say, six months later, the only evidence of tubercle found would be a fine epithelial pellicle in the lungs. Or the inoculation might be followed by rapid loss in weight, increasing cachexia, and death within six weeks, post-mortem examination then showing a generalised and rapid tuberculosis. In a series of nearly 100 cases thus examined the author had found that 62 per cent. owed their origin to the bovine bacillus. These cases have been drawn entirely from Edinburgh and its neighbourhood, and gave serious food for thought, for they could mean only one thing, a milk supplying infection to a highly dangerous degree. With regard to cases due to the human bacillus, in every case an inquiry was instituted into the question of tuberculosis among other members of the family, and it was found that in 71 per cent. there was a history of tuberculosis—usually pulmonary—in the family. The practical lesson to be drawn was the importance of isolating pulmonary tuberculosis. 2. Routes of infection. Bones and joints were rarely the site of the primary development of tubercle, when attacked it was secondary to some more distant infection, the vehicle of infection being the blood or the lymph stream There had been much controversy whether the bone or the joint was the first to become infected Experiment would appear to prove, first that it was difficult, often impossible, to infect the cavity of a healthy bone with tubercle the resistance of the marrow being too great and the bacilli becoming almost invariably destroyed Secondly, that the joints were readily infected through the blood stream the anastomosis of the circulus vasculosus in the fringes of the synovial membrane being more exactly the situation in which the disease begins Clinically, an osseous tubercle did occur, and the explanation was that while tubercle bacilli could not develop in a healthy marrow, when the marrow was altered disease might arise The change in the marrow was a gelatinous degeneration—a disappearance of the true marrow cells and a proliferation of the fibro myxomatous groundwork In a marrow so altered tuberculous disease readily developed This change was the result of an endarteritis and thickening of the vessels, nutrient or metaphysial, and a resulting interference with nutrition affecting respectively the diaphysis or the epiphysis The vascular thickening was due to the circulation of the tuberculous toxin The thickening of the nutrient artery might be secondary to tubercle anywhere, that of the metaphysial vessels usually arose from a focus of tubercle in the neighbouring synovial membrane Our experimental knowledge therefore of the etiology of bone tubercle indicated that synovial tubercle was readily produced and the synovial membrane was infected by the blood stream Healthy bone could not be infected with tubercle, its marrow must first undergo a gelatinous or fibro myxomatous degeneration, such as was occasioned by tuberculous endarteritis of the vessels nutrient or metaphysial, supplying the bone (b) *Pathology* —The disease might begin in the centre of the diaphysis or at the articular ends, in the epiphysis or at the metaphysis, depending on the site of the reflection of the synovial membrane—i e, whether the reflection lay only in relation to the epiphysis or extended beyond it to the metaphysis *Changes resulting from the lodgment of the bacilli* —The bacilli were probably originally deposited by a small extravasation of blood from a thin walled vessel such as occurs in a slight sprain There the bacilli developed forming a small tuberculous follicle, with giant cells epithelioid cells and lymphocytes It was important to emphasise that the primary lesion was a true follicle developing in the marrow As the follicle enlarged others appeared around it, forming a mass of appreciable size possibly apparent to the naked eye as a tiny white spot in the red marrow Coincidently caseation appeared at the centre an attempt at fibrosis and localisation at the periphery of the follicle If the central change preponderated the caseation extended rapidly throughout the marrow and ' infiltrating tubercle resulted, if the peripheral change the disease remained localised causing encysted tubercle But independent of the growth of the follicle coincident changes appeared in (1) the marrow, (2) the bone lamellæ (3) the periosteum and (4) the blood vessels and from these changes many of the clinical appearances gained their characteristic features The author proceeded to describe these changes at some length The marrow changes were a cellular reaction followed by a limiting fibrosis The lamellar changes consisted of absorption by osteoclasts or of surrounding hyperostosis by osteoblasts at a distance The periosteal changes were a subperiosteal limiting deposit of light cancellous bone The vascular changes were of the nature of endarteritis obliterans The best classification of the disease designated the various types by the most characteristic changes namely (a) *an encysted type* in which the disease remained localised, (b) *an infiltrating type*, in which it tended rapidly to spread throughout the lamellæ, (c) *a hypertrophic type*, in which the distinguishing feature was an overgrowth of bone, (d) *an atrophic type* in which a rarefactive process was most evident In regard to treatment there were two special points the author wished to bring out as they were more or less original First that the usual conservative treatment is absolute rest of the affected part Of the many materials used to ensure rest the ideal material must be light, well fitting, comfortable, and yet rigid Such a material was to be found in celloidin or pyroxylin or celluloid Batten (The Lancet, July 13th 1912) recommended celluloid splints in the treatment of infantile paralysis, they could be equally well used in bone or joint tubercle except in the hip, shoulder, or spine where they were precluded by the size and extent A special advantage was that they could be taken off and the part massaged a practice that had not hitherto received sufficient attention Secondly, the employment of a type of autogenous vaccine Bone tubercle was arrested and ultimately cured by a surrounding fibrosis which depended on the action of a specific element contained in the tissues which he believed would be present if the vaccine were prepared as follows A portion of the actual diseased tissue was ground up, the supernatant fluid was centrifuged and filtered sterilised by heating to a temperature of 50° C for one hour, and standardised by measurement (5 c c &c) Such a vaccine contained not only the toxin of the bacilli and the other bodies usually present, but also the special fibrous tissue forming element which he believed to be so important Clinically, its use had given excellent results —Mr Harold J Stiles said that infection of bone occurred very easily in children At first one got a toxæmia of tubercle from some other part of the body—e g glands This toxæmia produced endarteritis Tubercle began very rarely in the epiphysis itself, this was almost invariably secondary to joint disease Diaphysial tuberculosis was most frequent Was it infected secondarily to the joint or was it primary? He said that Mr Fraser had demonstrated and established the fact that 62 per cent of bone and joint tubercle was of bovine origin There was no question as to the human origin Another worker in Edinburgh (Dr K. Mitchell) had shown that 90 per cent of cervical gland tuberculosis was of bovine origin and these infections were due to tuberculous milk so that legislation as to the milk supply was necessary In Edinburgh with its more than 2000 cows, one inspector was required to do the duties while in the country there was no inspection whatever Even when a cow was found with a tuberculous udder there was no power to order its slaughter There was more tuberculosis in Scotland than in England and Ireland because more milk was drunk in this country Ayrshire cows were most frequently employed as milk givers because of their large yield, and in that breed tuberculosis was most prevalent

Leeds and West Riding Medico Chirurgical Society —A meeting of this society was held on Jan 17th Dr J Dobson the President being in the chair —Mr Alexander Sharp showed a number of skiagrams of the Mastoid Area A bismuth plug had been placed in the external auditory meatus before sending the patient to the radiographer A very distinct outline of the canal appeared on the negative This formed a useful guide to the mastoid antrum lateral sinus &c, and simplified the interpretation of the plate In some cases it might be more useful to smear the drum head only with the bismuth paste —Mr G C Hayes showed a case in which there had been a five months history of œsophageal obstruction A diagnosis of œsophageal epithelioma was made and this was confirmed by the œsophagoscope An operation had been performed by Mr J F Dobson and the growth which was an extensive one, successfully removed the upper end of the cut œsophagus being sutured to the skin The specimen was also shown —Mr Dobson also exhibited some cases showing the advantage of block dissection in the removal of cervical glands for malignant disease —Cases were also shown by Dr C Wilfred Vining, Dr A Bronner Mr Walter Thompson Mr J Basil Hall Mr H Littlewood Dr W H Maxwell Telling Dr T Wardrop Griffith and Mr Carlton Oldfield —A paper was read by Mr Oldfield on Obstetric Surgery its Uses and Limitations He discussed the treatment of eclampsia comparing the surgical methods of simple induction of labour, and of vaginal and abdominal Cæsarean section with expectant and therapeutic measures Pernicious vomiting of pregnancy he regarded as a neurosis and advocated treatment by full feeding and suggestion As a rule surgical interference was not indicated in this condition nor was it in fibroid tumours or in pyelitis complicating pregnancy The necessity in some cases for cranioclasty and decapitation was deplored The need for these could usually be avoided by examination during pregnancy, when Cæsarean section would be indicated.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 8th, Dr. Walter C. Swayne, the President, being in the chair.—Dr. J. A. Nixon gave a demonstration on the Technique of the Intravenous Administration of Neo-salvarsan. He stated that it was necessary in syphilis to give doses at intervals of a week or less until Wassermann's reaction had become negative, and remained so for at least four weeks, four or five doses being usually required.—Dr. C. W. J. Brasher, in a paper on Intermittent Swelling of the Parotid Gland, related the case of an adult female who had had attacks of acute parotid swelling at intervals for more than ten years. A vaccine of the micrococcus catarrhalis grown from the interior of Stenson's duct gave a year of freedom from attacks, but the condition had since recurred.—Dr. J. O. Symes said that he had seen a boy with bilateral parotid swelling occurring every evening for some weeks following an attack of mumps.—Dr. Carey Coombs said that he had seen a similar condition affecting the submaxillary glands.—Dr. R. S. S. Statham showed a specimen of Primary Rupture of the Pregnant Uterus before Labour. When the patient, who was eight months pregnant, was first seen she was thought to be a case of concealed accidental hæmorrhage, but a laparotomy revealed an extensive rupture of the uterus and the child free in the peritoneal cavity. She had been curetted a year previously for a septic abortion, and no other cause could be found.—Dr. F. H. Edgeworth related a case in which phosphaturia and oxaluria alternated, the latter condition being accompanied by renal colic and hæmaturia. The condition was cured by more complete mastication, the patient having previously bolted his food.—Dr. Brasher had also a case of oxaluria accompanied by hæmaturia and renal colic.

Reviews and Notices of Books.

X Ray Diagnosis and Treatment. By W. J. S. BYTHELL, B.A. Cantab., M.D. Vict., Honorary Physician to the Ancoats Hospital, Manchester; and A. E. BARCLAY, M.D. Cantab., M.R.C.S. Eng., Medical Officer to the Electrical and X Ray Departments, Manchester Royal Infirmary. With 118 illustrations. London: Hodder and Stoughton. 1912. Pp. 139. Price 15*s*.

OF the many books on X ray work we have had occasion to peruse we do not remember one that has so many pleasing features as that now under consideration. It would seem to have been the authors' constant care to say no more than it was necessary to say on any particular point, and to say it in the most clear and concise way. As the book does not pretend to teach the technique of radiology, we are spared a hundred or more pages of material that can be usually found in any text-book of physics and in an instrument maker's catalogue. The authors have drawn upon a large experience of their own, and confine their observations to that almost entirely, and there is never any difficulty in ascertaining their views regarding debatable matters. Another good feature is formed by the illustrations. These are all from striking plates made by the authors, are well reproduced, and conveniently placed in groups at the end of each chapter. On the subject of fractures the limitations of the value of a screen examination are emphasised. In a large proportion of cases only a plate of good quality can make the situation clear, and nothing less than this is admissible when the question of readjustment of the fragments by operative procedure arises.

X ray diagnosis in connexion with diseases of the bones and joints is thoroughly well dealt with. The loss of opacity that accompanies most bone diseases—notably tuberculosis—is well shown in the excellent skiagrams that illustrate this chapter. Wisely, we think, a special chapter has been devoted to the examination of the bones and joints in children. In no branch of radiography is a greater experience necessary than in the interpretation of plates made during the growing period, whether for accident or disease. The authors have done much to help in clearing the difficulties that surround this important subject.

Turning to the section of internal medicine there is a very useful chapter on the examination of the thorax. It is pointed out that it is in the more obscure cases that the aid of the X ray is desired, especially in the earlier stages. Phthisis is, of course, the most common condition that requires every available aid to assist the diagnosis. Defective lighting up of dark or mottled areas, restricted movement of the diaphragm, enlarged bronchial glands near the root of the lungs, are among the important signs that can be made out only by this method, and they go far to determine the nature of the case under investigation. This chapter is a valuable one. Dr. Barclay's work on the examination of the stomach and intestines is well known both at home and abroad, and we are fortunate in having his ideas so clearly and concisely stated in the chapter on the examination of the abdomen. In a sound chapter on the urinary system, we note that the authors state that in the examination for stone the error need not exceed 1 per cent. The therapeutic applications of the X rays are referred to in one short chapter, and there is a brief appendix on X ray apparatus and technique.

This book is meant for medical men generally, who wish to know how far the X rays may be of assistance in any case that appears likely to be benefited thereby. They need have no fear of being inundated with a lot of technical detail of no special interest to themselves. They will find every page interesting and easy to understand, and so great is the importance of radiology in modern medicine and surgery that many of our readers must be seeking just this work.

Practical Anatomy: an Exposition of the Facts of Gross Anatomy from the Topographical Standpoint and a Guide to the Dissection of the Human Body. By JOHN C. HEISLER, M.D., Professor of Anatomy in the Medico-Chirurgical College of Philadelphia. With 366 illustrations, of which 225 are coloured. London and Philadelphia: J. B. Lippincott Company. 1912. Pp. 790. Price 21*s*. net.

THIS work gives in one volume a full and fully illustrated account of the dissection of the entire body. It is doubtful if it is the wisest policy to issue a dissecting manual in a single volume, for it is necessary that the one book should be in constant use in the dissecting-room throughout the whole course of practical anatomy. The illustrations are all by Mr. E. F. Faber, and some are already familiar as figures in Piersol's Anatomy; some, however, are drawn especially for this volume. Mr. Faber's work is admirable, but in some instances the colour printing has hardly done him justice, for many of the figures show a bad overlap of colour. It would seem a mistake to colour the vas in Fig. 300 exactly like the veins, and so give the appearance of an anastomosis between the two structures. Some slight criticism must also be made concerning the index lines to the illustrations; Fig. 41, "ant. circumflex vein," is an instance. It is possible that individual copies vary somewhat, but in the one submitted for review this line appears to end on the brachial artery, and no vein seems to be indicated at this spot.

It was rather a surprise to us to see that a new work published in America did not embrace the B.N.A. terminology in its entirety, but the author's reasons for this are given clearly in his preface, and with these reasons we are in perfect accord. One piece of terminology has attracted our attention. The prominence over the joint between the manubrium and gladiolus of the sternum is named throughout as the angle of Lewis. The best warranted eponymous term for this angle seems to be the angulus Ludovici, which is usually anglicised as the angle of Louis, or occasionally by confusion the angle of Ludwig. We do not know to what anatomist named Lewis the author ascribes this term.

The book is well and carefully written, and many classical mistakes are avoided; we think, however, that the popularity of the book will be handicapped by the fact that several of the old strained positions are still retained for dissecting. With formalin as our stock preservative, it has seemed useless to continue the lithotomy position which is here advocated; the damage done to the hardened tissues is too great a price to pay for the retention of what is after all merely a traditional piece of surgical anatomy.

Preventable Cancer. A Statistical Research by ROLLO RUSSELL. London, New York, Bombay, and Calcutta: Longmans, Green, and Co. 1912. Pp. 167. Price 4*s.* 6*d.* net.

THE subject of the cause of cancer has an immense fascination for many, both of the medical profession and others. Mr. Rollo Russell some time ago wrote a book on the "Reduction of Cancer," and in the present volume he has put together many facts bearing on the question of the cause of malignant disease, supporting his opinion by statistics, which he has collected from a very wide area. The statistics relate to the distribution of cancer geographically, to the increase of cancer during recent years, and to its occurrence in various occupations and trades. Mr. Russell has arrived at the following conclusions. Cancer shows a graduated increase from extreme rarity to great frequency, according to the habits of nations, races, and tribes. Apart from exceptional customs, it scarcely exists among peoples and in districts and countries where the diet is natural, cool, and frugal, without irritating or stimulant adjuncts. The use of water as the staple drink is of effect in immunity. The increase of recent years corresponds with the regular and very large increase in the consumption of stimulant meats and drinks, of hot foods and drinks, and with the increased consumption of adjuncts of many sorts, including unwholesome forms of sugar, pickles, drugs, and preservatives. The author has evidently taken a great deal of trouble in preparing this little book. He has succeeded in showing, what has been shown so often before, that local irritation is an important factor in the production of cancer.

Handbuch der Vergleichenden Physiologie. Von HANS WINTERSTEIN in Rostock. Lieferung 25. Band I. Zweite Hälfte. Bogen 11–20. Pp. 161–320. Price 5 marks.—Lieferung 26. Band III. Erste Hälfte. Bogen 11–20. Pp. 161–320. Price 5 marks.—Lieferung 27. Band III. Erste Hälfte. Bogen 21–30. Pp. 321–484. Price 5 marks.—Lieferung 28. Band IV. Bogen 53–61. Pp. 841–976. Price 5 marks. Jena: G. Fischer. 1912.

IN the 25th Lieferung the editor, Professor Winterstein, continues his account of the Physico-chemical Phenomena of Respiration, in which those who wish for data collected from all the available sources will find what they seek. The remainder of the text is devoted to the Mechanics and Innervation of Respiration, which is entrusted to E. Babák, of Prague. The author, however, deals only with the subject from protozoa to the holothurids, so that students of respiration in the higher groups must wait for the continuation of the author's compilation.

In the 26th Lieferung R. du Bois-Reymond continues his account of the Physiology of Movement (see THE LANCET, March 2nd, 1912, p. 587). It is particularly interesting, as the author brings together an immense number of facts which an investigator would not readily find. The latter half of this part is devoted to the Production of Noises and Tones, by O. Weiss. No wonder the author refers to the impossibility of including all the observations. He begins with noises and notes produced by the arthropoda, and then deals with similar phenomena amongst the vertebrata. When Professor Weiss finishes his subject, two pages are left, and on the first of these Professor Biedermann, of Jena, begins a masterly and exhaustive contribution on the Physiology of the Supporting and Skeletal Substances, which occupies the whole of the 27th part. Even at the end of this part the author still finds himself dealing with the protozoa. This may give some idea of the thoroughness and completeness aimed at by the author.

The whole of the 28th Lieferung is assigned to Hearing and the Sense of Equilibrium, by E. Mangold, of Freiburg i. Br., who gives an admirable account of a difficult subject, requiring on the part of the reader a wide knowledge especially of invertebrate zoology. We find much to commend in the grouping of the extraordinary range of facts which the author has accumulated, the largest number of which has reference to the invertebrates. These functions in vertebrates are treated less fully.

Surgery of Deformities of the Face. By JOHN B. ROBERTS, A.M., M.D., Professor of Surgery in the Philadelphia Polyclinic, Surgeon to the Methodist Hospital, &c. Illustrated with 273 figures. London: Baillière, Tindall, and Cox. 1912. Pp. 273. Price 12*s.* 6*d* net.

SOME 12 years ago, when Dr. J. B. Roberts was appointed by the College of Physicians of Philadelphia to deliver the Mutter lectures, he took as his subject the plastic surgery of the face, and this book had its origin in those lectures. Although several excellent treatises on plastic surgery have appeared, there is still a marked tendency to underrate this important branch of surgery. The author of this work has written a very useful guide to the treatment of the deformities of the face, whether they are congenital in origin or have resulted from injury or disease. He has introduced the subject by a careful study of the face, for the surgeon who would become skilled in the plastic surgery of the face must first of all know the minute details of the face on which expression depends. Unless attention is paid to these details a certain degree of failure is always liable to follow attempts to rectify a deformity. The general principles of plastic surgery are explained, and then in turn the author takes the various lesions of the face and shows how they may be treated. A chapter on cleft palate is included. We are inclined to speak favourably of a practical book.

Pathology of the Eye. By P. H. ADAMS, M.A., M.B., D.O. Oxon., F.R.C.S. Eng., Consulting Ophthalmic Surgeon to the Radcliffe Infirmary, Surgeon to Oxford Eye Hospital. London: Henry Frowde, Oxford University Press, and Hodder and Stoughton. 1912. Pp. 194. Price 5*s.* net.

THIS book is a bold attempt to compress an account of the pathology of the eye, including bacteriology and practical methods, into 188 small pages of large print, the bolder in that many of the pages are almost completely occupied by illustrations. It cannot be said that Mr. Adams has succeeded. There are many lacunæ, much scrappy information, and some insistence upon views not generally accepted. For the most part, however, the information given is trustworthy, and the faults are chiefly faults of omission. A preliminary chapter deals with practical methods of embedding, and so on. (We do not agree with putting the bisected eye, after washing from formalin, into 70 per cent. alcohol.) The usual anatomical divisions are followed in the next eight chapters. Then come glaucoma, general diseases affecting the eye, and bacteriology. There are many references to recent work. Thus Thomson Henderson and Arthur Thomson's theories of glaucoma are discussed. The author pins his faith to the latter, though we think that many ophthalmologists will not agree with him. Further, the relatively large space devoted to Henderson's views might have been better employed in an elementary book for students, who will be unable to appreciate the difficulties of his theory without a previous discussion of the physiology of the intraocular pressure, and that we have been unable to find. The illustrations are from original photographs and are good.

Allgemeine Biologie. Von OSCAR HERTWIG, Direktor des Anatomisch - Biologischen *Instituts* der *Universität* Berlin. Vierte umgearbeitete und erweiterte Auflage. Mit 478 teilsfarbigen Abbildungen im Text. Jena: Gustav Fischer. 1912. Pp. 787. Price, paper, 19.50 marks; bound, 22 marks.

ONLY three years have elapsed since the third edition of this work was published. This, the fourth, has undergone considerable changes. The text has been here and there curtailed, but over 60 pages have been added, while the number of illustrations has been increased from 435 to 478. In order to bring the text up to date certain chapters have been expanded, such as those on the action of the β and γ rays on ova and spermatozoa; and those on the survival of tissues, and on the *in vitro* methods used, more especially by American investigators, to keep alive tissues removed from the body. The new facts about chondriosomes, dimorphism of spermatozoa, heterochromosomes, hormones, and secondary sexual characters and the doctrine of heredity have all been added to. Otherwise the general arrangement is the same.

The classification of the book as a whole is simple. The first part deals with the cell as an independent organism, and runs to about 450 pages; while the second part, the cell in union with other cells, occupies the rest of the volume. In connexion with the newer facts regarding the structure of the cell protoplasm, we would draw attention to the full account of those small, well-defined granules or shorter or larger thread-like bodies described by Benda and Meves in both animal and vegetable cells known as "chondriosomes" and "mitochondrian." Exactly in this direction great advances have been made recently. Moreover, the notes on this subject—as on all the other subjects set forth in this work—are illustrated by clear, well-printed illustrations in the text. In fact, the high quality of the illustrations is a striking feature throughout.

Histology and function, growth and repair, are considered together, so that we obtain a true biological conception of cell life and not merely a treatise on cytology, which is apt to become a rather sterile pursuit when treated solely from the morphological aspect. We do not find any material changes in the chapters on excitability and stimuli. The whole question of the development and the mechanism of division of cells is obviously expounded *con amore*, and, be it added, from an overflowing knowledge of those recondite processes as they occur in both plant and animal cells. About 80 pages are occupied with this subject alone, and nearly 100 pages are assigned to the phenomena of impregnation and fertilisation of cells, ranging through all classes of animals and plants. Parthenogenesis—both natural and artificial—is fully described, while due attention is given to Loeb's experiments on this and allied subjects. At the end of the first part the literature relative to each chapter is given seriatim and amounts to 20 pages of closely printed matter, and the same arrangement is adopted for Part II. (about 18 pages).

The second part is perhaps more interesting than the first, because there enters the question of the interaction of cells and all that this foreshadows. If the reader will turn to the excellent exposition of Weismann's germ plasm theory and to the chapters on the theory of biogenesis, he will find an admirable exposition of these abstruse subjects. Many illuminating pages are devoted to the external factors concerned in organic development"; in fact, the author out of the fulness of his knowledge makes us feel how few really know much about the subject. With equal facility he discourses on the inner or internal factors of organic development. We can merely refer to the thoroughness displayed in dealing with the facts, theories, and doctrines that surround the question of heredity, and the other score of questions that are treated in the remainder of the volume.

We offer to the author our thanks for the manner in which he has marshalled and expounded that immense—shall we say "kolossal"?—array of facts which for the present goes to make up what is called "general biology," a department of "natural science" to which he himself and his forebears made very material and extensive contributions.

Einführung in die Physiologie, Pathologie, und Hygiene der menschlichen Stimme. Von Dr. ERNST BARTH. Mit 260 Abbildungen und 2 farbigen Tafeln. Leipzig: Georg Thieme. Pp. 507. Price 15 marks.

THIS work, as its title would suggest, is divided into three parts. The first 317 pages are devoted to the physiology of the voice, and constitute, perhaps, the more important part. By way of illustrating the thorough and exhaustive nature of this section, it may be mentioned that not only the anatomy of the larynx is described, but that of the organ of hearing is also dealt with. The second part is given up to the pathology of the voice, and in about 124 pages one finds what is essentially a treatise on diseases of the larynx. The remaining 60 pages cover the hygiene of the voice, which includes the physiological importance of athletics upon the voice.

The book throughout is profusely illustrated, and contains a good index, which adds to its value as a work of reference. It is not only a demonstration of the affections of the voice, but also a treatise on the scientific investigation and treatment of the same. Although there has been no dearth of publications on this subject, those interested in it can undoubtedly turn to Dr. Ernst Barth's treatise with advantage.

The Treatment of Short Sight. By Professor Dr. J. HIRSCHBERG, Geheimmedicinalrath in Berlin. Translated by G. LINDSAY JOHNSON, M.D. Cantab., F.R.C.S. Eng. With 12 illustrations. London: Rebman, Limited. 1912. Pp. 123. Price 5*s.* net.

THIS brochure is an essay on short sight founded upon a lecture delivered in Berlin at the request of Professor von Leyden. It is a very sound presentation of the subject, characterised by scintillations of Professor Hirschberg's archæological and philological erudition, and permeated throughout by his forceful personality.

The essay begins with Galen and ends with Hirschberg, and in the 120 pages everything pertaining to myopia—history, optics, pathology, treatment—seem to be compressed. The style is stimulating, if at times irritating; but even where most dogmatic or most uncompromisingly critical of the teaching and treatment of other ophthalmologists there is generally sound wisdom at the foundation. Indeed, Professor Hirschberg's teaching is orthodox to a degree, and his strictures and sarcasms are poured out upon the ill-judged methods of enthusiasts. Thus, most surgeons will agree that in myopic detachment of the retina "the facts speak loud and clearly, the theories are debatable, the treatment risky, the cure rare." The author discusses the treatment of high myopia by extraction of the lens in a manner which will commend itself to those of a judicial mind His opposition to the operation appears to have increased with increasing experience He says. "From the close of 1893 to the commencement of 1901, I have relieved 24 persons in all from high myopia" by this method; and he adds in a note "Since then none! The more bad results I met with among the operations of my colleagues, the more did my hesitation increase'

But these are debatable points, and most of the essay deals with straightforward facts The descriptions of the causes of short sight, the damage done to various parts of the eye, preventive measures, and so on, are quite admirable, and the amount of useful information conveyed in a short space is truly remarkable Readers will be instructed and at the same time entertained by a perusal of the book The translator, the printer, and the publisher have done their parts well

---

Handbuch der Serumtherapie und Serumdiagnostik in der Veterinar Medizin Herausgegeben von Dr M KLIMMER Ord Professor, Direktor des hygienischen Instituts und der Seuchenversuchsanstalt an der tierarztlichen Hochschule in Dresden, und Dr A WOLFF-EISNER, Arzt fur innere Krankheiten und Vorsteher der bakteriologischen Abteilung des städtischen allgemeinen Krankenhauses Friedrichshain-Berlin Band II vom Handbuch der Serumtherapie Leipzig Dr Werner Klinkhardt 1912 Pp 500 Price, paper, 18 marks, bound, 20 marks

IN this text book edited and partly written by the above named authors assisted by 20 collaborators, three full page plates illustrate respectively the eye reactions in a tuberculous cow and a glandered horse, and the local reaction in a glandered horse from subcutaneous mallein injection

As is usual in German publications of the nature under notice protective and curative inoculations against hog cholera swine fever, and swine erysipelas receive full consideration, and they occupy the position of precedence in this book Writing from a general point of view, it may be stated that the inoculations, both preventive and curative, seem to be much more successful in the case of swine erysipelas than in those of the other two diseases Inoculations against anthrax and symptomatic anthrax (black quarter) are discussed in 20 pages of the text The chapter on protective and curative inoculation against foot and-mouth disease does not seem very practical to us, and no notice appears to have been taken of Dr Siegler's recently reported discovery

In testing cattle with tuberculin the temperature is to be taken, according to the author, every two hours from the sixth to the twenty second hour until the "critical" temperature is reached, and in animals where the temperature reaction is delayed and the "critical" temperature not yet reached observation must be conducted until the latter occurs or a decline of temperature is evident The trials with "abortin" undertaken by the English Abortion Commission are given in detail, but apparently, notwithstanding the favourable view of the results given, no further investigation has been undertaken in German circles The serum and vaccine treatment of streptococcic diseases, inoculations against calf diseases, the serum treat ment of fowl cholera, and the protective and curative inoculation against distemper of the dog are next considered With regard to the last named disease, although vaccines and sera seem to have been employed in plenty against it, most scientists declare unfavourably concerning them, as, indeed, one would expect, considering that the organism of distemper has not yet been widely identified even if discovered Tetanus antitoxin in stables infected with the organism seems to have given good results by its use, especially when combined with disinfection The use of mallein in glanders is fully dealt with, but although the names of Hunting and McFadyean appear once in the list of literature at the end of the chapter, no reference is made to Hunting's standard work on "Glanders," which may be due to the fact that the book has not yet been translated into German

There is a chapter on pyozyanase and its use It has been used beneficially in spray form and as an intravenous and intraperitoneal injection In surgery, midwifery, diseases of the ear, eye, and skin, in dentistry, in diphtheria, strangles of the horse, and distemper of the dog, the results from its application have been good Agglutination and precipitation, fixation of the complement, and anaphylaxia and anaphylactic shock are thoroughly considered in Chapters XXIX, XXX, and XXXI The rat and mouse exterminator will find a wealth of condensed information as to the destruction of these pests by the latest scientific methods within the pages of this book

The whole volume is a valuable literary mine of instruction as to the origin and preparation of animal products, and their therapeutical and diagnostic use on animals The organisms of distemper (N S Ferry) of foot-and mouth disease (Dr Siegler), and of Johne's disease (Twort and Ingram) may have been discovered almost simultaneously with the production of this work, and further valuable information may be expected

LIBRARY TABLE

The Land that is Desolate By Sir FREDERICK TREVES, Bart, G C V O London Smith, Elder, and Co 1912 Pp 287 Price 9s net —The "Land that is Desolate" is the Holy Land, a land about which more has been written, and to which more pilgrims have turned their steps, than to any other place in the world Sir Frederick Treves is already well known as the author of other books of travel, such, for instance, as "The Cradle of the Deep," a book dealing with the West Indies In that country he evidently enjoyed himself, but in the book now before us there are traces of disillusion And disillusion is, we fear, the lot of everyone who now goes to the Holy Places The hand of the spoiler lies heavy on the land, centuries of pilgrimage have vulgarised, for at least two great religions, the most sacred sites in the world, and finally, be it said with regret, nowhere else has the seamless robe of Christ been torn into more fragments Moreover, the faith or credulity of early days is wanting in these times Even the inexpressible charm of the East seems to have escaped Sir Frederick Treves in great part, and the filth, the squalor, the beggars, and the general nakedness of the land appear to have entirely obscured for the writer the attraction of the light, the colour, the transparent atmosphere, and the curious fascination of an olive grove The portions of the book which appeal to us most are the chapter upon the Jordan and the Dead Sea and those dealing with Damascus The river and the lake naturally figure largely in all accounts of pilgrimages to the Holy Land and Sir Frederick Treves will be interested, if he has not done so already, to compare his own impressions with those of Fabri, who visited the Holy Land about 1483 Both travellers tried the water of the Dead Sea, but with a somewhat different experience Sir Frederick Treves found the water in bathing "warm and very clear, but it felt oily or soapy the taste of the water was merely salt for some time after I had left the lake there was a sensation as if a mustard plaster had been applied to the shaven part of one s face" Now let us hear Fabri, who was not so daring as to bathe. "Whoever partakes of this water and places some in his mouth, at once finds the inside of his mouth corroded by reason of the excessive saltness as if he had taken very hot water, this I myself experienced Again "He who puts his hand in the water at once feels prickings, just as though his hand was covered with fleas and gnats, and he is obliged to rub them as if he had the itch, and this feeling endures for many hours, neither is it easy to wipe away this water from the hands, for it is just as though they had been rubbed with oil."[1] On most points it will be seen that across the gap of over 400 years the observers agree. In Damascus the call of the East does seem to have made itself heard, for Sir Frederick Treves gives a really sympathetic account of the site of the city and of the bazaars. He was unfortunate in the end of his journey, for he came in for a serious railway accident on his way to Haifa, and upon embarking at that port for a very severe gale. Possibly these unpleasantnesses have in some way influenced his book, which, well worth reading as it is, does not, in our opinion, do justice to its theme. We note that on p. 10 Sir Frederick Treves says: "No one knows where Tarshish was. ......" From an article which appeared in the *Times* about the middle of November, 1912, it would seem to be pretty well established that Tarshish stood where now stands Seville.

Lehrbuch und Atlas der Konservierenden Zahnheilkunde. Von Dr. GUSTAV PREISWERK. With 323 illustrations and 32 plates. Munich: J. F. Lehmann. 1912. Pp. 404. Price 14*s*.—This volume forms one of a series of handbooks of medicine published by Lehmann's, of Munich, and deals with the various operations embraced under the term "conservative dentistry." Dr. Gustav Preiswerk's name is sufficient evidence that the work has been well carried out. By means of semi-diagrammatic illustrations the different steps of the various operations are shown in a clear and instructive manner. The book may be of real value to the dental specialist.

Hoblyn's Dictionary of Terms used in Medicine and the Collateral Sciences. Fifteenth edition. Revised throughout, with numerous additions, by JOHN A. P. PRICE, B.A., M.D. Oxon., M.B. Lond. London: G. Bell and Sons, Limited. 1912. Pp. 878. Price 10*s*. 6*d*.—A factor in Hoblyn's Dictionary which has contributed largely to its arriving at a fifteenth edition is undoubtedly its literary quality, and this quality is continued in the present edition. As a companion to the medical reader who is not a profound student, however, we fear that the work may often prove disappointing. Its discrimination in eliminating terms the significance of which is presumably left to be inferred by a well-educated practitioner who also possesses a fair all-round knowledge of the subjects to which the medical terms relate is too great, and will render it an impractical rival to some of the newer dictionaries, which take little preliminary knowledge for granted. As an example of what we mean, we may point to the omission of such words as bactericidal, bacteriotropic, nidus, decinormal, hyperchlorhydria, ileocolostomy, leucopenia, zymase, oxidase, sympus, apus, and dipus, and very many others. As to eponymous terms, Trendelenburg's, Sims's, and Walcher's positions are now given. Of operations, very few are given, and those chiefly such as can be found in the ordinary textbooks; the newer ones constantly recurring in periodical medical literature are frequently absent. We still are unable to find Babinski's, Rovsing's, or Kernig's signs, Lissauer's, Bertin's, or Gowers's columns, Bassini's, Kraske's, or Stacke's operation, and many others. The first person singular of Greek verbs is still translated by an infinitive. Although the extension of bacteriological science is referred to in the preface, only 25 bacilli and 4 bacteria are mentioned. Hippuris (equisetum) finds its place in alphabetical order, but hippuric acid has to be looked for under hippo. We fail to see why zymic acid should be given only as zumic, seeing that in all other words the Greek υ is transliterated y (zymosis, zymome, zymotic, zygoma, &c.). On p. 877 ξυγός is given for ζυγός, a printer's error. As we said in reviewing the former edition, the book will be of great service in reading the older writers in medicine, but we fear it will have to undergo complete reconstruction and enlargement if it is to compete for the favour of the general medical reader with the newer medical dictionaries.

Diet Charts: For the Use of Physicians. Compiled by J. CRAIK TAYLOR, M.B. Glasg. Glasgow: John Horn. Price 1*s*. net.—These diet charts are drawn up for use in fevers, convalescence, and dyspepsia, for constipation, and other conditions. The intention is that the practitioner who uses them shall either strike out or underline the food materials which are suggested in the charts. It is a question whether the diet of a nursing mother need be as circumscribed as suggested in these charts, but they serve, at any rate, as a reminder to the practitioner of many items of diet the advantages or disadvantages of which should be considered under different conditions.

The Student's Guide to Life Assurance in Theory and Practice. By ARTHUR WYNDHAM TARN, F.I.A. London: Macdonald and Evans. 1912. Pp. 224. Price 3*s*. 6*d*.—This book is mainly concerned with a consideration of life assurance from the point of view of the actuary. It is a good guide to the study of the elementary principles of insurance. The medical examiner, as a rule, confines himself to a statement whether, after due inquiry and examination, the life may be considered an average one or below the standard, and troubles himself but little as to the actuarial side of the question. It is desirable, however, that a medical man who undertakes a fair amount of life assurance work should make himself acquainted with the elementary principles upon which the mortality tables are founded, and those on which the calculations of premiums are made. In Mr. Tarn's work much interesting information will be found in regard to these matters, but the greater part of the book is taken up with material that concerns the actuary and his assistants only. There is a chapter on the medical aspect of life assurance; some of the remarks to be found therein are of value, although they are brief, such as the observations on "family history," but the "medical views as to treatment of impaired lives" are too sketchy to be of value to the examiner. The last section of the work is taken up with a statement of the salient features of other branches of insurance.

La Vie du Règne Minéral. By RENÉ SCHWAEBLÉ. Paris: Jules Rousset. 1913. Pp. 118. Price 3 francs.—This product of the modern French School of Neo-biology is a treatise on "Mineral Biology: the Life of the Inanimate." The idea is an ancient one and may not appear altogether incredible to those who have realised how largely the energy of organic growth and development is derived from mineral substances. The little book is full of interest and stimulating thought, although one can hardly be expected to take the author seriously in his excursions into the realm of alchemy and the transmutation of metals. As might be expected, the subject of osmotic growth is very fully treated, and the book is illustrated by some very interesting pictures of Leduc's beautiful productions.

MISCELLANEOUS VOLUMES.

LITTLE books on big subjects in their physical and moral relations are brought out to-day in great abundance. A selection of those which have reached us recently may be conveniently reviewed in association with each other.

In the volume entitled *Morals and Brain*, in the series of "New Tracts for the Times" (London: Cassell and Co. 1912. Price 6*d*. net), Sir THOMAS CLOUSTON gives an admirably clear and simple account of what science has to teach concerning the relationship of moral conduct to the action of the brain in health and disease The most urgent bio social problems that we have to deal with nowadays are, as we are coming more and more to recognise, in the main, problems *of character, and, so far as they admit of the application of* preventive measures to the generation already in being, they are problems of ethical training in youth and adolescence For this reason it is of the utmost importance that the social reformer and the philanthropist should understand the physiological basis of character and the conditions which influence its development This excellent little volume will furnish that knowledge in an easily assimilable form, and its perusal should go far to dispel some of the remarkable illusions which, as the debates on the Mental Deficiency Bill have shown, are still cherished even by sapient legislators —— It is to be regretted that the author of *Can a Drunkard be Cured?* Mr E BROWN, M R C S, L R C P (London Francis Griffiths 1912 Pp 85 Price 2s 6d net), who is a medical man and presumably intends to treat his subject from a medical standpoint, should not have displayed a similar moderation and accuracy He has, however succumbed to the evil tradition which leads so many persons, when they write about alcohol, to adopt the phraseology, and in a large measure the intellectual standards of the teetotal tract The work, it is true, is addressed mainly to actual or potential drunkards and this fact may possibly explain, if it does not justify, the use of an emphatic and rhetorical style as an aid to suggestive therapeutics Devices of this kind, however, are rather prone to react on the writers who have recourse to them and may beget a tendency to exaggeration of statement, and there are evident traces of such an influence in Mr Brown's book It is an obvious exaggeration, for instance to assert that half the insanity of the country is caused by drink or to suggest that prostitution is mainly due to alcohol, and it can hardly profit the cause of sane temperance, and is assuredly irrelevant to the reform of the inebriate, to draw lurid pictures of the dangers that surround "the so called moderate drinker' With regard to the special subject of the book, the treatment of the drunkard, the author has nothing very novel to say, except that he lays rather more stress than is usual on the value of auto suggestion, from which he claims to have seen permanent results

[1] Fabri Evagatorium, Ed. Hassler, vol. ii., pp. 154, 155.

By all those who have long realised that the housing difficulty lies at the root of many of our social problems Mr RAYMOND UNWIN's pamphlet, *Nothing Gained by Over crowding* (London Garden Cities and Town Planning Association 1912 Pp 20 Illustrated Price 3d) will be read with the greatest interest because he has there set out to prove that even from the economic standpoint nothing is gained by putting as many houses as possible on a given area When houses are built in long serried ranks, as is the case in the poorer parts of all large towns, the expense of road making is very great because such a considerable proportion of the ground must be occupied by roads in order to provide sufficient frontage for the large number of houses, whereas by the system of grouping the houses and giving more space for gardens and public recreation grounds less amount of road making is required, and consequently the expense is diminished Mr Unwin has himself given practical demonstration, both at Letchworth and at Hampstead, of his theory that there is no economic obstacle in the way of limiting the number of houses or other buildings to be erected on a given area of land, and the space thus saved from road making can be devoted to gardens and public recreation grounds When the number of houses to the acre is limited the builder s profit either on the buildings themselves or on the increased value of the land due to development will not be reduced if the profit be estimated per house instead of per acre Limiting the number of houses per acre renders each individual plot large enough to hold quite a *considerable sized house, but it is important to check* the tendency to build houses of larger size than are required by the necessities of the district Hence in addition to restricting the number of houses per acre it is wise also to limit the number of cubic feet of building to the acre This principle is in some measure observed in the Town Planning Act of 1909 and in the regulations of the Garden City at Letchworth ——Mr H CORBIN, B Sc Lond, D P H, medical officer of health of Stockport, in a useful paper on *Housing in Practice* (London 1, Upper Montagu street, Russell square Pp 16), lays stress on the necessity of pure air adequate light, and cleanliness in the dwelling and work place as essential for the prevention of tuberculosis and the reduction of infant mortality, he might also have added as one of the best means of promoting temperance Like Mr Unwin, he emphasises the advantages of limiting the number of houses per acre, and insists on the importance of local authorities purchasing as much land as is available in and around their areas, and also exercising care in the selection and supervision of tenants in the houses of the poorest class As he well says "the existence of slum dwellings encourages the indolence of those who find it less trouble to live at ease in the squalor of a slum dwelling for which they pay 2s a week than to work a few days more and live in a better house with a more wholesome environment at a rent of 4s 6d a week" Both these papers are well worth careful study by all social reformers The principles which they advocate may be found exemplified in the Garden City at Letchworth as one result of which the infant mortality does not exceed 54 5 per 1000 ——*Fresh Air and How to Use It* is the title of a book by Dr THOMAS SPEES CARRINGTON (New York 105 East Twenty second street 1912 Pp 250 Price $1) in which the various plans for obtaining fresh air by the modern house-dweller are described Ventilation, window tents, roof bungalows, wall houses, permanent sleeping porches, methods of screening porches tents, roof playgrounds and open air cottages are described and illustrated, and suggestions are made for the planning of new houses with open air apartments

---

JOURNALS AND MAGAZINES

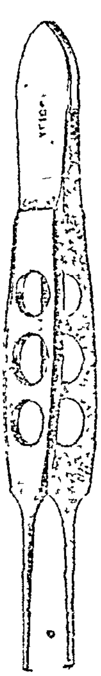
The Quarterly Journal of Medicine Edited by WILLIAM OSLER J ROSE BRADFORD A E GARROD, R HUTCHISON, H D ROLLESTON, and W HALE WHITE Vol VI, No 22 January, 1913 Oxford At the Clarendon Press Subscription price 25s per annum Single numbers 8s 6d each —The contents of this number are 1 Study of a Case of Dyspituitarism by Gerhardt von Bonin An exhaustive account is given of the pathological features found at the necropsy of a case presenting the clinical characters of benign acromegaly which had been observed by Mr Frank Corner for over 20 years The physiological and pathological effects of the hypophysis upon the various functions of the body are fully discussed The paper is one of special interest and is accompanied by a useful bibliography Among the general conclusions arrived at are that there are hardly any cases of pure hyper pituitarism or of pure hypopituitarism both processes being generally found together Sexual infantilism and *adiposity* are symptoms of hypopituitarism and are usually found to be associated with acromegaly which is the result of hyperpituitarism It is suggested that this is accounted for by Cushing s theory, that one secretion of the pituitary body enters the blood directly whilst the way for the other to the third ventricle is blocked by the pressure of the tumour upon the infundibulum. 2. The Fragility of the Red Blood Corpuscles, by G. G. Butler. It is found that the fragility of the red corpuscles is extraordinarily constant in normal and pathological conditions, but a number of general conclusions in regard to an increase or decrease of fragility are given. 3. Iron in the Blood, by P. H. C. Fowell. As a result of a long series of estimations with Autenrieth's instrument, it is hoped that its value has been proved for the clinical estimation of iron in the blood, and that Biernacki's statement, that estimations of the total iron give no true index of the hæmoglobin value, has been confirmed. It is also shown that in all individuals there is an excess of iron in the blood over that which is combined with hæmoglobin, and that this excess bears a varying ratio to the total amount of iron. 4. Premature Ventricular Beats in Heart-block, by A. E. Naish. A case is recorded and numerous tracings and electrocardiagrams are figured and discussed. 5. Observations on Auricular and Nodal (?) Extra-systoles, by E. E. Laslett. 6. Exceptional Types of Slow Heart Action, by Thomas Lewis. 7. A case in which a High Speed of the Auricles did not Produce Tachycardia, by William E. Hume. 8. Congenital Family Steatorrhœa, by A. E. Garrod and W. H. Hurtley. The case of a boy, aged 8 years, presenting a true steatorrhœa from infancy—i.e., the passage from the bowel of liquid fat which solidifies on cooling—has been carefully studied. It is suggested that the boy is the subject of a rare inborn error of fat absorption, probably a Mendelian recessive characteristic, and on a par with such anomalies as alkaptonuria and cystinuria. 9. Critical Review: Artificial Pneumothorax, by E. Rist, from the Laennec Hospital, Paris. After a historical sketch of the evolution of this method of treatment a clear description of the technique of the various methods used in its application is given. The accidents, difficulties, and complications are then considered, and a discussion of the selection of cases suitable for its employment follows. Other matters dealt with include the clinical results and duration of treatment, the morbid anatomy of the lung in cases treated by it, and the theoretical explanation of its therapeutic effects. The bibliography accompanying the article extends to 67 publications.

Le Nourrisson. Edited by A. B. MARFAN. Paris: J. B. Baillière et Fils. Published every two months. Price 12*s.* per annum (14*s.* for foreigners). A new review, bearing the above title and under the editorship of Dr. A. B. Marfan, will henceforth be published six times a year in Paris. The publication of a journal devoted exclusively to the medical aspects of infancy is quite a new departure in the annals of pædiatrics. The growing importance of the subject which this journal embraces, and the vastness of the literature which accumulates on matters relating to infant mortality and infant morbidity, certainly warrant the publication of a periodical which shall deal exclusively with these subjects, and the leading part that Paris has played in all international efforts to improve the conditions of infant life makes it peculiarly appropriate that the French capital should be the birthplace of this new journal. The first number, published in January, contains several original articles on practical matters relating to the hygiene and pathology of infancy, of which the most important are one on a Case of Congenital Stenosis of the Pylorus, by Dr. Marfan and Dr. Baudouin, and a second on the Control of the Rearing of Infants (Contrôle de l'Élevage des Nourrissons), by Dr. E. C. Aviragnet, general secretary of the League for the Prevention of Infant Mortality in France. A considerable part of this number of the review is taken up with some sound *résumés* of important articles from the general literature bearing on the subject. The first number augurs well for success and we offer the editor and his staff our congratulations.

New Inventions.

THE FINGER GRIPS OF FORCEPS.

THE finger grips or plates of forceps have many varieties of markings thereon to ensure a proper hold of the instrument. The old file markings that were in almost universal use are now considered taboo in these days of "aseptic handles" (although it is curious to note that similar serrations still are retained as indispensable at the business ends of the blades). File markings have been succeeded by various breadth and depths of flutings, or by a broad shallow groove extending the whole length of the finger plate. Neither of these grips proves satisfactory; they are barely sufficient when the fingers are dry, they are inefficient when the fingers are wet, and a hold is impossible when the fingers are slippery. For some years I have been using sundry eye instruments and forceps in which the finger grips were secured by cutting holes in the flat plates. My experience of them has been most happy; they are superior in security to even the old file markings. The illustration shows a pair of iris forceps of the pattern used as conjunctival forceps in my new squint operation of subconjunctival reefing. The holes are cut square-edged and give a most sensitive grip—in fact, "grip" is a poor word in its suggestion of strenuousness; even when the fingers are wet, or purposely slippery, it is possible to hold these slender forceps accurately. The holes lighten the instrument, a matter of some consideration in eye work, and they are obviously clean. The size of the holes can be made large in proportion to the size of the forceps. The forceps are made by Messrs. Weiss and Son, Oxford-street, London, W.



Harley-street, W. N. BISHOP HARMAN, F.R.C.S.Eng.

NEW TOURNIQUET FOR INTRAVENOUS INJECTION.

THE pneumatic tourniquet here illustrated has been designed by me for use in giving an intravenous injection. I found on more than one occasion that, after having passed a cannula needle into a vein, the movement during the release of the ordinary rubber tourniquet resulted in the needle piercing the wall of the vein, or even leaving the vein. To obviate this I devised the pneumatic tourniquet. It consists of a tube of firm rubber connected by a smaller tube to an inflating ball. In the smaller tube is placed a three-way valve tap, so that the pneumatic tube can be inflated, kept filled, or deflated by a very small movement of the handle of the tap. The pneumatic tube is loosely attached to a firm band of webbing fitted with a buckle to fix on the upper arm. In use the webbing band covering the tube is fixed loosely in position and the latter inflated by pressing the ball; the valve is turned into the mid position, and in a few seconds the veins are made prominent. After the selected vein is punctured the valve is again turned to the third position, when the tube becomes deflated and the venous circulation of the limb recommenced and the injection given. The deflated tube remains in position until the injection is finished, thus obviating any movement of the limb whilst the needle is *in situ*, the whole cycle being worked by the operator with ease. I have used this tourniquet now many times and find it answers all the requirements I wished. The appliance has been made for me by Mr. J. H. Montague, 69, New Bond-street, W.

THE LANCET.

LONDON · SATURDAY, JANUARY 25, 1913

The National Insurance Act.

THE administration of medical benefits under the National Insurance Act is now in some sort of working order, the probability being that in those places where the old relations of *medical men to their patients* have been least troubled the Act is working best, while in those places where the maximum alteration in previous conditions has occurred, as in certain of the London districts the machinery is still very imperfect. This is, of course, not the ideal result of a great measure of reform, though it must be allowed that such complexities of routine as have been necessarily introduced into professional life could hardly be expected to produce anything at first without considerable trouble Much or all of the trouble could have been avoided if the *measure* had been *inspired* by better knowledge and passed into law after due deliberation, but no practical point is served by keeping up this cry, save where it can be rightly used in any move for necessary amendment

In another column there will be found an account of the critical meeting of the Representative Body of the British Medical Association, at which it was finally determined that the restrictive power of the pledge and undertakings demanded last year by the British Medical Association hould be removed The meeting was a private one and asted two days The proceedings, as will be seen by the account of our representative, whose presence was courteously permitted, were throughout of an anxious character, as it was impossible for the Representatives not to feel that great nterests were involved, and that obvious solutions for some difficulties would have merely aggravated other difficulties perhaps of equal importance During the first of the two days, during which the Representative Body was in session, attempts were made to arrive at some middle course whereby hose who thought that the pledge should be maintained in ull force and those who thought that it should be abrogated might fall into some common line of action It was felt to be necessary, in the position in which the British Medical Association was placed, not to ostracise or even blame those who had already gone upon the panels, as it was known hat many of them had given their names in unwillingly But it was necessary also to recognise that those who had emained off the panels had done so from a high conception f their duty to the Association and from a belief that he existing scheme for the administration of medical enefits is a menace to the progress of medicine Various motions and amendments to motions were brought forward n the effort to find some mid way which should be equally cceptable to both parties, but all these debating ontrivances were of no avail

Eventually, and not till the second day of the session, a resolution was obtained by 115 votes to 35—a majority sufficient to make the action of the Representative Body binding upon the Council and members of the Association—in favour of releasing all members of the medical profession from their pledge and undertakings, a reversal of policy which it had been widely foretold was inevitable All men are therefore now at liberty to go on the panels, although they will do so with the remembrance that they are serving under Regulations which are termed by the Government "provisional" This vote of the Representative Body has, we believe, enabled adequate panels to be formed in different parts of the country, even where this had not already occurred, but in London the revolt against the working of the Act is maintained, and the composition of some of the panels remains unsatisfactory

◆

The General Practitioner and Operative Surgery.

A PROMINENT American surgeon, after an extended and recent tour through England, remarked, on his return home, upon a thing that struck him with surprise in the medical practice of this country He found the extent to which, *even in country districts nearly all the operative work* was sent off at once to some hospital or infirmary, instead of being undertaken, at any rate as regarded the simpler cases, by the local practitioner, dificult to comprehend He did not attribute this to any lack of competence for in many cases not only did the practitioner hold distinguished surgical qualifications, but intercourse with him showed him to possess a high standard of surgical knowledge But few if any medical men, he said, of equal calibre in America would deprive themselves of the continuous growth of experience or of its legitimate recompense which such a course entailed, or would subject their patients to the many disadvantages incident on removal to an alien environment If a case came within the reasonable capabilities of a medical man, and anything approaching satisfactory—not necessarily ideal—environment was obtainable, the practitioner in America would operate He attributed the British practice to an abnormal sensitiveness to responsibility resulting from submission to a convention inherited from a past age, when the average general practitioner was less highly educated in surgery and had rarely enjoyed the opportunities for gaining practical experience afforded by a good residential appointment Partly right in his views, our American critic left out of his calculations the curious passion that exists in many localities for criticising the medical practitioner while ignoring his difficulties

This subject was ably discussed last week at a meeting of the Medical Society of London, reported elsewhere in this issue, by Mr T NORTH, in a paper on the Rise and Possibilities of the General Practitioner Surgeon Mr NORTH pointed out that between the rich, who could afford to retain the services of any surgeon whom they might know by reputation, and the very poor, who, if for no other reason than the absolute impossibility of their surroundings and the inevitable lack of nursing, must continue to go to hospitals for serious operative measures, there existed a large and rapidly increasing class of people who, though unable to afford the pure surgeon's fees, could afford fees for surgery that would be accepted by the general practitioner, and whose means and mode of life made possible the provision of a satisfactory environment and proper nursing. By their resort to hospitals the hospitals are overcrowded and compelled to spend at an unnecessarily high rate, the honorary surgeons have more work to do from which they receive no financial return, while the general practitioner is deprived of fees he might fairly enjoy for work that compares favourably as to its responsibility with that entailed by a difficult confinement. There can be no doubt that much of MR. NORTH'S plea, in which these things were put out, is sound. The high level to which medical education has been raised of late years means that, in the case at any rate of the by no means insignificant number who have held good resident appointments, satisfactory surgical work can be done if the local environment of the patient is suitable, and if intelligent assistance with trained surgical nursing can be got. The extension of the cottage hospital system would do much to meet the case. It would ensure the presence of adequate nursing in the locality, establish a sufficient amount of proper assistance, including the development of a local semi-professional anæsthetist, and might render available to all local practitioners access to those special means of diagnosis and treatment which are too costly for him to invest in for himself, having regard to his limited opportunities for using them. It would also afford shelter in cases where the patient's domestic arrangements could not suitably be made to meet the case.

We agree with MR. NORTH that the relations of consulting surgeons and general practitioners would be greatly improved by the extension of operating by competent general practitioners, and we think it possible, also, that the consulting surgeon would really be the gainer financially through the frequency with which he would be called in for consultation upon patients who, if they came into his hands for operation, could not afford his fees, and must, therefore, be operated on by him in a hospital for nothing. Also the time at his disposal for the consideration and development of original thought and procedure would be increased. The advantage to the public, too, would frequently be great, for the patient would often gain by remaining at home and the avoiding increased nervous dread. Moreover, as great surgical experience as possible in the general practitioner is desirable in the interests of all classes of the community alike; for persons of no class are exempt from the danger of serious emergencies involving immediate surgical intervention, and it is obvious that emergency operations are even more dangerous to life, and call for even greater surgical skill and resourcefulness than those for which adequate preparations can be made, and time, place, and assistance carefully selected. We feel constrained, however, to demur to the individual instance of what one must call malpractice on the part of a hospital operating surgeon adduced by MR. NORTH to strengthen his argument in favour of the general practitioner-surgeon doing his *own surgical* work. It is obvious that no general conclusion can be drawn from such a case, even though it be true, because it cannot rightly be alleged that such a thing often happens. A like mode of argument might easily be made to favour the abolition of the entire medical profession. But this is merely an instance of the all too common tendency to strain a point in favour of the thesis advocated. MR. NORTH'S admirable paper is convincing enough without it, and if read with a fair and open mind should do much to arouse a sympathetic interest in the subject.

The German Imperial Insurance Act.

THERE has been presented to Parliament during this week a report dealing with medical benefit under the German Sickness Insurance legislation, which deserves the study of all our readers, for any information upon the administration of medical benefits under an insurance system is extremely valuable to us. It cannot be too often repeated that the Regulations under which our own National Insurance Act is being worked are provisional in their nature, and it is certain that considerable amendments must be made if the prognostications of some of us prove unfortunately true, while the most ardent supporters of the Act, those who appear to consider that a noble object is a sufficient excuse for any unfortunate coincident occurrences, admit that in so elaborate and far-reaching a measure it is inevitable that modifications will have to be made. Now it is an open secret that much of our own legislation has been inspired by the German pattern. It is, therefore, particularly interesting to look closely at that pattern, and the Commissioners of the National Insurance Act have done well to publish this report, and place the situation as they see it freely before the public.[1] As the German Insurance Consolidation Act, though passed in 1911, will not come into full operation until the beginning of next year, the report deals with the statutory Sickness Insurance Organisations as they exist and are working at the present time, but a note warns the reader that where the new law alters the constitution of those organisations, or such of their duties, powers, or methods of procedure as specially affect the administration of medical benefit, the changes are indicated in the report in brackets. The report is based upon inquiries made personally in a number of towns in various parts of Germany, the towns being chosen with a view to ascertaining the experience of important Sickness Insurance Organisations differing in character and in methods by which the medical service is organised and remunerated. Local medical associations and representative local practitioners have been consulted, and, as a result, it is clear that there are many points of difference between the insurance legislation of Germany and of England.

For several years past THE LANCET has by articles under various headings kept its readers informed with regard to the progressive development of State insurance in the German Empire. By a coincidence in the same week that a report by our own Government on the subject reaches us, we have also received two volumes[2] in which the provisions of the Imperial Insurance Act (*Reichsversicherungsordnung*) are set forth. In view of the dissatisfaction of so many British practitioners with the insurance statutes which have become operative here, the books in question deserve attention as showing what steps have been taken by foreign medical men under similar circumstances and as being illustrative also of the latest Government report. The existence of considerable differences between the British and German systems has been frequently mentioned in our columns. For instance, under the British system old-age pensions are granted without previous contributions by the pensioner, whereas in Germany they are contributory, and the administrative body which grants them is also concerned with invalidity pensions, but not with insurance against sickness. In Great Britain, moreover, no precise distinction is made between sickness and invalidity. In the title of Dr. RUMPF's book R.V.O. stands for Reichsversicherungsordnung, and the work itself is divided into the three sections of (1) Sickness Insurance, (2) Accident Insurance, and (3) Invalidity Insurance, with Old-age Pensions, and Assistance for Widows and Orphans. Of these the first is no doubt the most important to the medical practitioner. For many, if not most, of the lower-paid occupations it is compulsory, while for others it is optional. Insurance is compulsory (1) for workmen in general (*Arbeiter*), assistants, apprentices, domestic servants, and home workers; and (2) for the following when their regular earnings do not exceed 2500 marks (£125) per annum: the office staff of business houses or manufactories, foremen, shop assistants and apprentices, druggists' assistants and apprentices, theatrical and orchestral employees, teachers and tutors, and the crews of vessels, whether foreign-going or engaged in inland navigation. Insurance is optional for (1) healthy persons belonging to the working-class, but for some reason not coming under the compulsory law; (2) members of the family of an employer and engaged in his business without remuneration; and (3) tradesmen and other owners of businesses not regularly employing more than two compulsorily insured persons. These voluntary insurers, however, must not have an annual income exceeding 2500 marks, and are subject to certain restrictions as regards health and age.

---

[1] *Medical Benefit* under the German Sickness Insurance Legislation. His Majesty's Stationery Office. Price 4½*d*.

The administration of the sickness insurance, although controlled by the State, is not in the hands of any State-appointed individual or association, but is assigned to self-governing sick clubs (*Krankenkassen*), of which five varieties are specified. The clubs decide what amount shall be paid as the contributions of the insured persons, provided that it does not exceed 4½ per cent. of the wages, except that in the so-called local sick club (*Ortskrankenkasse*) the contribution may, with the joint consent of the employer and the insured person, be as much as 6 per cent. of the wages. Dr. RUMPF has a good deal to say about the difficulties with which the club medical officers have to contend, and Dr. PLAUT is particularly full on this aspect of the question, his well-timed book being mainly an account of the operations of the great medical protection society, the Leipziger Verband, with whose operations our readers are familiar. Dr. PLAUT quotes freely from official correspondence and gives particulars of negotiations brought to a successful issue against the strenuous opposition of club committees who study economy without considering the adequacy or otherwise of the remuneration offered to their medical advisers. No one can read the two books here noticed, side by side with the Report of the National Insurance Commissioners, without feeling that we have before us, and may have for some time, a great deal of difficulty in the administration of medical benefits; and also that the British service has to work out its own salvation, and cannot trust much to the German pattern, as in Germany different conditions obtain.

Annotations.

"Ne quid nimis."

BATH REDIVIVUS.

THE discovery of the strongly radio-active properties of the Bath thermal waters opens up an obvious opportunity for developing the resources of the city, and for this purpose it may be hoped that the authorities will receive unstinted and widespread support. The waters have been under the careful observation, of course, of the medical man and the chemist for some time past, but while the former knew what favourable therapeutic results in many classes of cases the waters, either by immersion or ingestion, were capable of producing, the latter could only supply a statement of analysis of negatively therapeutic constituents. As was pointed out some years ago in these columns, the composition of the Bath waters did not show any unique constituent present in important quantity, and, in fact, resembled that of many of the ordinary hard water drinking supplies in the country, which, of course, possess no special therapeutic value. It was concluded, apart from the reinforcements of treatment by diet, regular exercises, and so forth, that externally the waters were effective because they exercised a stimulating effect on the circulatory and nervous systems, helping in this way the absorption of chronic exudations, while internally their effect was regarded as merely that due to the ingestion of regular quantities of warm water promoting the removal of waste products, flushing the excretory organs, and tending to keep a regular state of the bowels. For a while our hydrotherapeutic authorities had to be content with some such explanation as this, though they had to admit that it was not a very illuminating one, as in many cases the favourable results of treatment were definite enough to point to a special therapeutic property of an agent inherent in the water itself. It is highly probable that this agent in the case of the Bath thermal waters has now been disclosed by the researches of Sir William Ramsay, who found that the waters showed an unusual degree of radio-activity due to the emanation of radium called niton. It is true that, regarded from the ordinary therapeutic standpoint, the quantity of emanation is small, but as further researches have shown, it is endowed with enormous energy, and on this account exerts intense effects which appear to be directed chiefly to promoting healthy tissue activity. Already some remarkable developments in administering the energies of the emanation have been adopted, while further methods have been suggested which promise a greater economy in treatment. At Bath, for example, the gas bubbling through the water has been allowed to escape for centuries, carrying with it the valuable emanation. This is now collected and stored in steel tubes to be used in conjunction with spray applications. Moreover, the emanation particles are strong positive charges, and therefore if the patient be insulated and charged negatively a maximum absorption of the radio-activity may be gained. Then the fact that the emanation is rapidly eliminated from the system by the lungs, skin, or other channels indicates that in internal treatment the efficiency would be increased by taking small doses of the water at short intervals instead of a large dose over a long period. The therapeutics, however, of radio-active administrations are still obscure, but enough has been cited to show that at Bath there are obvious facilities for obtaining such treatment in cases where relief may be considered probable or possible. The treatment of certain cases at Bath is notoriously successful, amongst which may be included in particular chronic gouty and rheumatic affections, where a direct relationship to the radio-activity of the waters exists. Bath, in short, possesses a natural asset of undoubted value in the treatment of disease, and this fact should stimulate the authorities concerned to put their house in order, consistently with the medicinal advantages offered. The English spas languish, not because they are without real natural therapeutic resources, but because the attractive accommodation, social attractions, and *régime* of the "Kur," which are the co-essentials of success at the foreign health resorts, are not forthcoming. We should like to see our country awake to this matter and making more effort to realise the benefits of the great natural therapeutic endowments which we possess. Bath has a peculiar opportunity at the present time. The prosperity of the city is founded on the splendid traditions of its past, on the reputation of its healing waters, now enhanced in the light of modern researches. The progressive policy which we have indicated is obvious.

THE TRUTH ABOUT COCOA.

Mr. Eugen Sandow, who, as our readers know, has no claims whatever to being a dietetic authority, has been busy "warning" the public through the channels of advertisement against the adulterations of cocoa, which he states are abundantly in evidence. The warning amounts to alleging that (we use his own words) "a very large proportion of the cocoa consumed in the fond belief that it is a pure unadulterated preparation of the natural cocoa bean, in reality contains an added drug which not only is unnecessary but actually detrimental from a health point of view." More recently he has quoted our own columns as a "striking corroboration of public warning." The quotation, we find, is taken from an annotation as far back in THE LANCET as June 20th, 1896, in which the use of alkali in cocoa was dealt with. Mr. Sandow's "added drug" is "alkali." We absolutely and positively affirm that the generality of the cocoas made by manufacturers of repute and sold on the English market do not contain alkali. We do not pretend to say that alkali is not used in the manufacture of some cocoas, but even if that is the case the finished product could never contain alkali in the sense which Mr. Sandow means to convey to the public. It is true we issued a protest 16 years ago against the use of alkali in cocoa, but, as we have since been careful to point out, the inference drawn by the public that free alkali was present in cocoa was based on a misconception of analytical results. This misconception still exists in some minds, and even in the scientific and technical literature on the subject the articles may be construed to imply that cocoa contains alkali. But the explanation as to how the misconception arose is perfectly simple, and we had hoped that it had been removed by our own contributions on the subject. We refer Mr. Sandow to an article on cocoa which is much more recent than 1896, an article entitled "Cocoa, Chemically and Physiologically Considered," which appeared in THE LANCET of Jan. 7th, 1905. He will find that there was not a particle of evidence that free alkali was present in 11 cocoas purchased on the market. There was abundant evidence, on the other hand, showing that the natural organic salts of the cocoa had been materially increased as regards both some of the English and Dutch manufactured cocoas. These salts (potassium tartrate or citrate, for example) are converted into alkaline carbonate on ignition, and it is this fact which has led to the fallacious belief in free alkali being present in cocoa. Of such cocoas it would be just as true to say that they contain alkali as it would be of wood because it yields pearl-ash or potash on burning. It would be equally reasonable to say that there was alkali in claret (an acid fluid) or tea, because the ash of these contains potassium carbonate. Mr. Sandow's cocoa also contains these salts, for while it does not contain alkali any more than the other cocoas we have examined, yet on incineration the ash is found to be strongly alkaline. Our analysis of the cocoa in question[1] showed that the alkalinity of the ash was equivalent to 2·82 per cent. of potash (K_2O), which is as high as most of the cocoas we examined. As already mentioned, we are not prepared to state that alkali is not used in the preparation of cocoa. We believe on the evidence of the best authorities that in some cases it is, but we are confident in asserting that this alkali is not contained in the cocoa as it is sent into the market by well-known manufacturers. The public, we are convinced, need have no fears of Mr. Sandow's "drug alkali" being present in by far the great majority of cocoas on the English market. It is time that this juggling with the word alkali in connexion with cocoa ceased, and that false alarms should be exposed. There is no justification at all for using the word alkali except in connexion with the true oxides of sodium, potassium and so forth—the caustic alkalies—and the presence of these in cocoas is inconceivable.

THE TREATMENT OF EPILEPSY.

IN the *Archives de Neurologie* for December last M. Maurice de Fleury, of the Académie de Médecine of Paris, has published an account of his successful treatment of idiopathic epilepsy by a combination of vegetarianism with the administration of lactic ferments. Starting with the hypothesis—for it cannot be said that the author's contentions are adequately proven—that in every case of idiopathic epilepsy a degree of meningo-encephalitis exists, dating either from intra-uterine life or from the first few months after birth, and that this lesion acts as a focus of irritation when the organism is in an unhealthy state from intestinal auto-intoxication, M. de Fleury has concentrated his attention on the latter condition as *agent provocateur* of the fits, leaving bromide or similar sedative, the action of which is solely on the organic hypersensibility of the cerebral cortex, to a large extent aside. His views of the pathogeny of epilepsy, it may be remarked, receive support from the recent experiments of M. Claude and M. Lejonne, who made subdural injections of chloride of zinc in dogs, thus determining a mild meningo-encephalitis of the motor area. This was always followed by a series of convulsive attacks, which gradually diminished and finally disappeared, the animal seemingly returning to perfect health. Then, after an interval of months the same animals received minute doses of strychnine paste in their food, with the result that they soon developed fits again and died in status, whereas control animals receiving identical strychnine doses, which had not, however, been previously injected with zinc chloride and developed meningo encephalitis remained entirely normal. The analogy which these carefully devised experiments present with what is so often seen in man—viz., convulsions in infancy from which complete recovery is apparently made to be followed by the recrudescence of convulsive attacks after an interval perhaps of years—is sufficiently close to claim attention. M. de Fleury, like every physician, has been duly impressed by the frequency with which gastro enteric disturbances are encountered in idiopathic epilepsy, and he regards these as the exciting cause of cerebral attacks although it is difficult to specify the exact nature of the poison. It is probable that intestinal putrefaction, as evidenced by the common occurrence of indicanuria, is the main source of trouble, and accordingly the author has made systematised efforts to modify the intestinal flora. He has now given up the lacto ovo vegetarian *régime* as disappointing and unsatisfactory, and retains the patient on a strict vegetarian diet with no food of animal origin. It comprises soups, farinaceous food, fresh vegetables, salads cooked or uncooked, fruit cooked or uncooked, honey, preserves and confectionery. There is, of course, nothing novel in such a *regime*, for as long ago as 1724 Cheyne in his famous "Essay on the Gout," and many others since then have enjoined similar suggestions on their patients. Vegetarianism by itself, however, is, in the opinion of M. de Fleury, insufficient. He recommends drinking not less than one litre in the 24 hours of some sweetened mineral water, to be taken in small quantity with meals and more freely between meals. Further, he strongly advocates lactic ferments in liquid form rather than as tablets and recommends they should not be too acid. Intestinal disinfection carried out in this way has proved eminently useful in his experience and a number of clinical cases are quoted to bear this out.

MAGNESIUM INFILTRATION.

THE general aim of the medical profession when confronted with an illness is to be able to say with Othello, "It is the cause, it is the cause, my soul,' for if the cause of a pathological condition be known the medical attendant is far on his way towards being able to remove or obviate the consequences. At varying intervals we are told that some condition is a cause in general of a multiplicity of abnormal conditions and this multiplicity has been ascribed to such different conditions as floating kidney, uric acid, eyestrain and the wearing of too tight a collar. It is probable that there is a modicum of truth in all these theories, for in so complicated a machine as the human organism an identical cause may produce very varying results, just as a small fragment of "dirt" may impede or destroy the working of a motor car by giving rise to abnormalities in very various parts of the machine. The most recent theory of a general cause is that put forward by Dr. John Aulde[1] in a work entitled "The Chemic Problem in Nutrition." Dr. Aulde's theory, we gather, is as follows. That alkalescence of the body fluids and tissues is the keystone of health, that the contrary of alkalescence is acid excess, that 'magnesium infiltration being the direct and immediate effect of acid excess it follows that it must be a concomitant of all disease processes" (p. 11 *et seq.*). The way in which the magnesium acts is as an insulator, the nerve becoming electro plated with magnesium oxide. Hence the normal nerve stimuli are inhibited and the tissues are coincidently affected so that they cannot do their proper work, whereupon a diseased condition follows. In infections this weakened condition favours the entrance of bacilli. It follows upon this reasoning that the main line of treatment in all diseases is to neutralise acid excess and promote magnesium dissociation. Dr. Aulde's theory is ingenious, but we fail to see that he offers any proof that in disease the nerves are electro plated with magnesium oxide and in his anxiety to support his arguments he now and then makes statements which are, to say the least of it, doubtful. His views are interesting to read, but we must add that in our opinion they must be held to be at present "Not proven."

THE SIGNS OF ORGANIC NERVOUS DISEASE IN SYDENHAM'S CHOREA.

THERE are not a few text books of medicine enjoying a deserved popularity to day in which it will be found that ordinary chorea, Sydenham's chorea or chorea minor, is classified among the functional diseases of the nervous system and placed between hysteria on the one hand and habit spasm on the other. At the same time it has long been recognised that there are certain features in the disease, apart from its association with rheumatism, which suggest an organic basis for the affection. Occasionally such complications as paralysis, amyotrophy, trophic disturbances, and certain psychoses ensue and these do not accord with the conception of a purely functional disorder. Yet it is only within the last decade that serious endeavours have been made to detect in chorea such symptoms and signs as are now accepted as indicative of organic disease of the cortico spinal and other motor paths. MM. H. Grenet and P. Loubet have written an instructive little paper on the subject, which appears in the *Revue Neurologique* for Dec. 15th, 1912. There are signs both of pyramidal and of cerebellar irritation to be found in Sydenham's chorea in addition to changes in muscle tone that seem to be definitely of organic origin. It is naturally in cases of hemichorea that the examiner can best establish the presence or absence of the following signs, for he can compare one side with the other. There is nearly always hypotonia of the affected limb, say the arm, which shows itself by the lowering of the shoulder and by the possibility of exaggerated flexion or extension of the forearm. The hypotonia is particularly well seen, as a rule, in the supinator group, the pronators retaining their normal tone. Thus if the arms are held vertically above the head the sound limb (hand) takes up the usual position midway between supination and pronation, while the affected hand becomes pronated. Combined flexion of the thigh and the trunk, so frequently seen on the affected side in organic hemiplegia when the patient, with his arms folded, endeavours to rise from the supine to the sitting position, is frequently to be observed in chorea. Again, syncinesis or associated movement—the affected side making the same movement as the sound side—is sometimes seen in chorea. Plantar extension also, it is agreed, is by no means rare in this disease. The writers have found Babinski's sign present in 19 cases out of 74. Strumpell's sign—contraction of the tibialis anticus when the patient's attempt to flex the leg on the thigh is resisted by the examiner's hand placed on the anterior aspect of the thigh above the knee, the foot going into a position of equino varus—is also to be noted in chorea. On the other hand, the condition of the tendon reflexes is inconstant and variable. As for cerebellar symptoms, defects of synergy are common enough. Dysmetria—i.e., overaction of various muscular groups in such a movement, say, as that of grasping an object—has been found in chorea in a number of instances. Similarly, there is sometimes inability to execute a succession of rapid identical movements, such as rotation of the forearm from the elbow (adiadococinesis of Babinski). No doubt the presence of abrupt involuntary movements may mask these others during testing, and, apart from this. it appears that not all of the signs above enumerated are of equal value. The presence of an extensor plantar response is, of course, highly significant. The presence of hypotonia also is worth noting, although in young children there is a greater range of passive movement than in the adult. If, however, there is a definite difference between the two sides of the body, muscular hypotonia must be considered an important sign. It is less easy to assert that cerebellar disturbances characterise Sydenham's chorea. As a general rule, if the patient is able to make slow alternations of movement well on either side, but fails on one or other in rapid performance of the same, true adiadococinesis must be admitted to occur, and it is clearly a sign of organic defect. In an investigation of 74 cases MM. Grenet and Loubet found muscular hypotonia 51 times; adiadococinesis 43 times; syncinesis in about half the cases; dysmetria in 25; Oppenheim's and Babinski's signs each 19 times; combined flexion of the thigh and trunk in 16 cases; and Strümpell's sign in 9. It may be said, therefore, that in Sydenham's chorea one or other indication of pyramidal or cerebellar defect is to be found in almost every case.

THE NATURE AND CAUSATION OF BLACKWATER FEVER.

IT is a matter of common knowledge that at the present time there is a diversity of opinion among medical authorities as to the precise nature and causation of blackwater fever, some maintaining that the malady is directly related to malaria, while others contend that it is in all probability a separate disease due to an as yet undiscovered specific organism. It is, however, generally agreed that blackwater fever is only met with in persons who have either suffered from malaria or who have lived for some time in a region where they must have been exposed to malarial infection. Recently Sir William Leishman has found cell-inclusions in the blood of some patients suffering from blackwater fever, and has discussed the possible nature of these bodies at a meeting of the Society of Tropical Medicine. He suggests that they may be indications of the invasion of the cells by parasites of the class to which Prowazek has given the name of Chlamydozoa. Blackwater fever is not infrequently encountered in our own colonies in the tropics, and this fact led a short time ago to a suggestion being made to our Colonial Office by the Advisory Medical and Sanitary Committee for Tropical Africa that detailed information bearing upon the disease should be collected by the medical officers in these African colonies with a view of throwing further light upon so important a subject. In consequence of this suggestion a circular letter was despatched by the Secretary of State to the Governors of seven of our African dependencies and protectorates, in January, 1911, requesting that the principal medical officers of each should be instructed to prepare and to forward annually to the Colonial Office a special report upon the occurrence of blackwater fever and the circumstances associated with it in his colony. The particular points to which attention was to be directed were set out for the guidance and assistance of the medical officers. The first series of these reports has now appeared, having been published by the Colonial Office[1] in a special paper. Some of the reports are very interesting; but in a collective investigation of this kind some time must necessarily elapse before sufficient evidence has been accumulated upon which to base conclusions. The difference of medical opinion to which we have already referred is illustrated by some of the communications received. For example, Dr. J. Wallace Collett, acting principal medical officer of Sierra Leone, expresses his belief, the result of 17 years' experience of blackwater fever, that this disease is not directly related to malaria and is not caused by the malarial parasite. He believes that it may possibly be due to a specific microbe which as yet has not been detected, but he is inclined to regard the malady rather as a symptom of a peculiar condition of the blood in a person whose constitution has become debilitated from a variety of causes, or a combination of causes, operating upon the bodily health. Though malaria has always been in his own mind intimately associated with blackwater fever, the virus of malaria, in his opinion, has no direct or specific action in the production of the malady in question. On the other hand, Dr. A. D. Milne, principal medical officer of the East African Protectorate, states that the theory which presents itself to his mind with regard to the factor producing blackwater fever is that it depends upon a liberation into the plasma of a sufficient accumulation of some toxin produced by the malarial parasite. This latter view has received the support of some of the best known of the authorities, who have made special investigations into the disease, but further evidence obviously will be required before it can be regarded as fully proved. The accumulation of facts in the first instance, as is now being done through the Colonial Office, together with the collation and careful study of cases, seem to offer the best chances of arriving ultimately at a trustworthy decision. Meanwhile this collective investigation must in any case greatly advance our knowledge of the disease, and we have little doubt that before long a solution of the problems will be forthcoming.

COMPLETE DISLOCATION OF THE INNOMINATE BONE.

IN the *Australasian Medical Gazette* of Nov. 23rd, 1912, Dr. Thomas Fiaschi has reported a very remarkable accident—complete dislocation of the innominate bone. A boy, aged 10 years, was walking along a street bounded by a galvanised iron fence. A sudden gust of wind blew the fence down and the upper edge struck him above the left crest of the ilium. He was taken to the Sydney Hospita with an abrasion of the forehead, a wound of the upper lip, and an irregular bony projection over the left sacro-iliac synchondrosis. On trying to move the projection slight crepitus could be felt. Movements of the hip-joint were free, but any handling of the left lower limb caused pain in the region of the left sacro-iliac joint. He passed urine freely without any blood in it. On the following day he seemed fairly comfortable. A radiogram showed that the left os innominatum was detached at the symphysis pubis and sacro-iliac synchondrosis. The whole bone seemed to be elevated half an inch at the pubes and one inch at the level of the iliac crest. Under ether the displaced bone was brought down. Three assistants held the boy firmly—one at the loins and one at each lower limb, pulling apart—while Dr. Fiaschi by manipulation brought the bone downwards and forwards. He was able to make the two pubic bones level He then applied a double spica plaster-of Paris bandage and a very strong pelvic band During this manipulation, whether because the assistants got tired or the boy's muscles suddenly contracted, the bone seemed to slip partly back, for a slight inequality could be felt at the symphysis pubis After a month the plaster was removed and a second radiogram was taken, and showed that the dislocation, though less than at first, was still present A projection could still be felt above the left sacro-iliac synchondrosis However, the boy seemed very well and could walk with a slight limp Complete dislocation of the innominate bone is very rare Recovery after it is still rarer, because it is usually accompanied by severe complications, such as rupture of the iliac vessels, bladder, urethra, or rectum In this case the cause of the dislocation was evidently direct violence The blow of the galvanised iron fence on the back of the left crest of the ilium in a young subject lacerated the soft ligaments Dr Fiaschi thinks the dislocation first took place downwards, but owing to contraction of the abdominal muscles and sacro spinalis the bone was drawn up into the position in which it was found It is noteworthy that no fracture was present Dr Fiaschi did not made a second attempt at reduction after the bone slipped back, because he had no reason to suppose that the same would not recur again He did not resort to Lane's plates over the symphysis pubis and between the crest of the ilium and the sacrum, because he feared that it would be difficult in a little boy to prevent soiling of the wound by urine and fæces, which would have been dangerous Moreover, he believed that even if the displacement was uncorrected little functional loss would follow The result proved that this was correct If the patient had been a girl he would have done more in view of the prejudicial effect which alteration in the pelvic diameters might have on labour It appears that only about 20 cases of this dislocation of the innominate bone are on record, and little is said about treatment Brnbach has recorded two cases In a man, aged 21 years, the left os innominatum was displaced upwards, backwards, and outwards Continuous extension of the lower limb was adopted Reduction was incomplete, but he recovered with a solid pelvis and only slight lameness In the second case the patient was a man, aged 44 years, and complete reduction was obtained by means of Schede's extension table It took place with a characteristic snap He was kept for a fortnight in plaster of-Paris, and for the remainder of the month on extension The pelvis recovered its normal shape and solidity, but neuralgic pains and atrophy of the limb remained

THE PROBLEM OF SPONTANEOUS GENERATION

THE experiments of Pasteur and Tyndale have for the last 40 years or so been almost universally allowed to afford proof of the impossibility, under our present conditions of knowledge, of the occurrence of abiogenesis Dr H Charlton Bastian is, we believe, the only eminent man of science in this country who still holds the opposite view, and only so lately as Nov 19th, 1912, he read a paper before the Pathological Section of the Royal Society of Medicine, in which he related experiments and defended his thesis with unwearied energy In September, 1912, Professor Schafer, in his presidential address to the British Association, stated with regard to spontaneous generation, "Our mistrust of such evidence as has yet been brought forward need not, however, preclude us from admitting the possibility of the formation of living from non living substance" In October, 1912, there was issued what the author modestly calls a "petit opuscule" by Dr H Grasset, entitled "A Historical and Critical Study on Spontaneous Generations and Heterogeny"[1] The gist of Dr Grasset's contention is that heterogeny and spontaneous generation, although hitherto they have been confused, are not the same Spontaneous generation is the generation of a living organism at the expense of mineral matter or of organic (not organised) matter which is dead This, says Dr Grasset, has not been demonstrated, "and I know of no proofs in support thereof" But heterogeny is e production of an organised individual without parents (*dénué des parents*), the issue of organic still living matter The major portion of Dr Grasset's book consists of a careful and methodical survey of the doctrine of spontaneous generation and of the arguments and experiments for and against the same from the days of Anaxagoras 500 B C to the present day Life, says Dr Grasset, following the views of Mialhe and Béchamp, is physiologically a universal fermentation, and the ferment, or that which plays the part of the ferment is the *microzyma* which is the real primordial element of animated life—that is to say, the vital molecule Therefore, continues Dr Grasset, in order to realise a true spontaneous generation we have only to create a microzyma and such a creation he considers within the bounds of possibility For already plasmogenists, especially Charlton Bastian, have created the *forms* of torulæ and microbes, and the function of a ferment has been artificially brought about by chemical or electrical methods; therefore, once we are able to unite the form and the function the problem is solved But the method by which this union is to be accomplished is still to seek In an addendum to his work Dr Grasset discusses Dr Bastian's experiments and results He believes that Dr Bastian has obtained living beings which are unable to resist the heat to which he subjected the solutions employed, and further, that he made no error in technique, so that external infection is out of the question But, says Dr Grasset, "Ch Bastian considers this a case of archebiosis, I think it only a case of heterogeny" And his explanation is that the organisms obtained by Bastian are due to microzymæ Whether or not Dr Grasset's views are correct, time alone can show, but in any case his little book is a most interesting and valuable contribution to the study of a yet unsolved problem

BILATERAL PARALYSIS OF THE THIRD NERVE IN TYPHOID FEVER

PARALYSIS of cranial nerves is a very rare complication of typhoid fever At a meeting of the Société Médicale des Hôpitaux of Paris on Dec 6th last, M A Lemierre M E May, and M Colet reported the following case in which bilateral paralysis of the third nerve occurred A girl, aged 18 years, was admitted into the Cochin Hospital on May 13th, under the care of Professor Widal A fortnight previously her illness began with pains in the left lower limb and shivering For eight days she was completely constipated Then she was given a purgative and an enema, and from that time there was profuse diarrhœa During the last ten days she was prostrated and somnolent and complained of violent headache On the fourteenth day epistaxis occurred On admission she was pale and weak The temperature was 103 6° F and the pulse 96 There were no signs of typhoid fever Some sibilant rhonchi were heard at the right apex On the seventeenth day of the disease the serum gave the typhoid reaction, but blood culture was negative On May 16th rose spots appeared on the flanks The disease ran a protracted course On June 13th, the forty seventh day of the disease, the temperature was 102·8°, and for the first time nervous symptoms were observed. Previously docile, the patient became bad-tempered. She refused to drink and acted like a child, complaining without cause, and lamenting if her desires were not granted. On the 15th the condition of childishness increased. She complained of violent headache and suffered from photophobia. She could not bear to be touched; there was manifest hyperæsthesia. In the afternoon ptosis of the right eyelid was manifest, and the pupil on that side was dilated, but it reacted normally to light and on accommodation. Inward rotation of the eyeball was lost and rotation upwards and downwards was diminished. Thus there were paralysis of the levator palpebræ superioris and internal rectus, and paresis of the superior and inferior recti, and the nerve supply of the constrictor of the pupil was affected. There was, therefore, paralysis of the third nerve. There was no paralysis of the left eye. Lumbar puncture was performed and yielded normal fluid. The patient became delirious, and on the 20th ptosis of the left upper lid was observed, but movements of the eye were normal. On the 21st movements of the left eye were slow and paretic, showing paresis of superior, inferior, and internal recti. The knee-jerks were absent. On the 22nd the left superior and inferior recti were completely paralysed, and the left pupil was sometimes dilated. The patient was somnolent and replied with difficulty to questions. The temperature was 103·1°. On the 23rd there was difficulty in swallowing; milk could be taken only in small mouthfuls, and some of it flowed back. On the 24th there was complete paralysis of both third nerves. On the 25th the patient died comatose. A necropsy was not obtained. Few cases have been recorded of ocular paralyses in typhoid fever. Hervieux described paralysis of the left third nerve in a fatal case of typhoid fever.[1] Lloyd published a case of isolated paralysis of the sixth nerve,[2] and Cormack described the same lesion with paralysis of all four limbs. Difficulty of deglutition in relation with paralysis of the soft palate is not so rare. It may occur with multiple paralysis of the limbs, producing more or less exactly "Landry's paralysis," or it may be accompanied by laryngeal paralyses or dysarthria. Cranial paralyses in typhoid fever are probably not always due to the same cause. Pathological observations on the subject are still rarer than clinical. It is known that typhoid infection may give rise to cerebral hæmorrhage, which is, no doubt, sometimes a cause.

---

[1] Etude Historique et Critique sur les Générations Spontanees et l Hétérogénie Par le Dr H Grasset Paris: Jules Rousset 1912 Pp 192 Price 4 francs

A STUDY OF THE BLOOD IN A CASE OF SEVERE HÆMORRHAGE.

The opportunities for studying the blood after severe uncomplicated hæmorrhage are not very frequent. Hence the importance of the following case reported in the *Boston Medical and Surgical Journal* of Dec. 5th, 1912, by Dr. J. Earle Ash from the Laboratory of the State Hospital for the Insane, Norristown, Pennsylvania. A young woman suffering from a functional psychosis was seized with pain in the epigastrium and vomiting. At the same time a vaginal discharge of thick, brown gelatinous mucus appeared. In about 12 hours the pain became generalised over the abdomen, and there was considerable distension. The pulse became small and rapid and she was very pale, the mucous membranes appearing practically bloodless. There was no elevation of temperature, the abdomen was not rigid, and only slight general tenderness could be elicited. In spite of the history, which seemed to discredit the possibility of pregnancy, a tentative diagnosis of ruptured ectopic pregnancy was made. The abdomen was opened about 24 hours after the onset of symptoms; much clot was removed, and ruptured right tubal pregnancy was found. 1·5 litres of saline solution were administered by the bowel, and uninterrupted recovery followed. The amount of the hæmorrhage could not be exactly estimated, but it considerably exceeded a litre. Just before the operation, about 24 hours after the onset of hæmorrhage, the leucocytes numbered 40,000. After the operation a series of blood examinations were made. Eighteen hours after the operation the hæmoglobin was 25 per cent., the erythrocytes numbered 825,000, and the leucocytes 24,400, of which 92 per cent. were polymorphonuclear neutrophiles. Other examinations were made 24 hours, 2 days, $2\frac{1}{2}$ days, 3 days, $3\frac{1}{2}$ days, 6 days, and 2 months after operation. The amount of hæmogobiln was respectively 25, 28, 30, 28, 30, 30, and 75 per cent.; the erythrocytes numbered 870,000, 1,830,000, 1,740,000, 1,950,000, 1,800,000, 2,550,000, and 4,310,000; the leucocytes 18,600, 15,200, 14,000, 12,600, 8000, 11,800, and 6800; and the polymorphonuclears were 91, 87, 81, 72, 82, and 58 per cent. Analysis of the facts observed showed the following: (1) High leucocytosis after the hæmorrhage which diminished consistently and fell to normal on the fifth day after the onset; (2) an increase in polymorphonuclear neutrophiles; (3) a low percentage of transitional forms in the early counts (1 per cent.); (4) an extremely low number of erythrocytes with absence of nucleated cells; (5) a low percentage of hæmoglobin which persisted for several weeks. Leucocytosis following acute hæmorrhage was described by the older writers such as Virchow. The following figures have been given by more recent writers; 41,000 leucocytes one hour after severe hæmorrhage, dropping to 14,000 in five days; 32,600 following hæmorrhage from cancer of the uterus; and 26,500 in hæmorrhage due to gastric ulcer. The extent of the leucocytosis is in proportion to the severity of the hæmorrhage. There does not appear to be any completely satisfactory explanation of the leucocytosis. It may be due to concentration of the leucocytes already present in the blood or to the discharge into it of cells held in reserve to meet such an emergency. Most observers have found numbers of nucleated red cells, except in cases terminating unfavourably. It has even been claimed that when the red cells fall below a million with absence of erythroblasts the case is always fatal. The one now recorded is an exception. The restitution of the number of erythrocytes to normal is much slower than the disappearance of the leucocytosis, and generally takes from 16 to 20 days. The development of hæmoglobin is still slower, the new erythrocytes being poor in this substance. This is shown in the figures given above.

The King has given His Majesty's Royal licence and authority to Llewellyn Powell Phillips, M.D., B.C. Cantab., F.R.C.S. Eng., Professor of Medicine at the Medical School, Cairo, to accept and wear the Insignia of the Third Class of the Imperial Ottoman Order of the Medjidieh, which decoration has been conferred upon him by His Highness the Khedive of Egypt, in recognition of valuable services rendered.

Professor Arthur Keith, M.D., has been elected President of the Royal Anthropological Institute of Great Britain and Ireland.

University of London: King's College.—A course of four lectures on Recent Advances in Chemical Physiology and Pathology will be given by Dr. Otto Rosenheim in the Physiological Laboratory, King's College, London, on the following Monday afternoons at 4.30: Feb. 3rd, 10th, 17th, and 24th. These lectures are free to all medical students in London medical schools, and to all internal students of the University of London, and to medical men on presentation of their cards.

NECESSITY OF A BETTER CLASSIFICATION OF EPILEPTICS

BY W. ALEXANDER, M.D. R.U.I., F.R.C.S. ENG.,
SUPERINTENDING MEDICAL OFFICER, EPILEPTIC COLONY, MAGHULL.

THE disastrous and pernicious custom of mixing up sane epileptics with imbeciles and epileptic lunatics, not only in the same habitations but also in the same literary and mental categories, is one that should cease.

Until December, 1888, when the first colony for sane and educable epileptics was established at Maghull, epileptics in this country whose relatives and friends could not look after them drifted to the imbecile or lunatic wards of asylums and workhouses, and certificates of insanity or of unsound mind containing the word "epileptic" did not require much other evidence to render them valid. The striking symptoms of a fit were quite sufficient to place on a par mentally and physically the sane epileptic, the insane epileptic, and the epileptic imbecile. It has often happened in the past that an epileptic, who appeared to the alienist under whose care he was to be sane, has been admitted for some action supposed to be a mad one by frightened or interested relatives or friends. Such a history, together with the alienist's knowledge of how many insane epileptics or imbeciles he has had under supervision, naturally will lead to the conclusion that although the state of mind of the particular case was very fair, yet as he was still an epileptic and liable to repeat the deed for which he had been sent to the asylum he could not be discharged. Besides, the alienist would reflect that, according to his knowledge of the disease, time would soon bring about the state of dementia to which, according to the prevalent opinion, all epileptics are liable, and therefore it would not be wise to take any risks.

With a better knowledge of epilepsy it is horrible to contemplate the condition of many poor epileptics in the past when there was no redress and no help, and when the effects of their environment often produced that dementia which the alienist ascribed to the disease. Our experience has amply proved the prevalence of this erroneous conception of epilepsy amongst all classes of society at the present time. For instance, when we first established our colony at Maghull the popular idea amongst the native population there was that the inmates of our homes were mad, and they wished walls built all round the place lest the sight of our patients working in the field should upset the course of nature in the observers. It was only when our patients beat the youth of the village at games that they were looked upon as rational beings. When we first placed a number of our patients under the charge of our farmer to dig up a lawn his good humoured tolerance of our belief that such patients could work was amusing to contemplate, and certainly the result of his management of them confirmed the bailiff's impression. When it was proved that they could and would work, his belief in their sanity took root and flourished. The same prejudice had to be eradicated in turn from the minds of all our officials. Again, when we established our school even the education authorities did not look upon the teaching seriously. They insisted strongly on drill, kindergarten work, and other interesting playthings, but the teaching of the "three R's" was preposterous in their sight. They went on the supposition that the children were all imbeciles and idiots and that the "three R's" were useless and impossible. It was only by examining the schools ourselves and insisting on progress in reading, writing, &c., that we were able to resist the powerful influence of the Board of Education, an influence due to a false conception of the mental capacities of sane epileptics. Paradoxical as it may seem, the Board insisted on highly paid and highly certificated teachers who were to spend the time on trifles and inanities that were looked upon as puerilities by most of the pupils.

"Psychic equivalents" of epilepsy, mistaken relationship.—The symptoms of epilepsy being so striking, it is not surprising that anything which occurs to an epileptic, connected or not with a fit, should be considered as belonging to the disease. Thus, if an epileptic becomes maniacal, it is called "epileptic mania"; if he be the subject of delusions unconnected with a fit, it is called a "psychic equivalent" of epilepsy; and if an epileptic—or, indeed, anyone who has ever had a fit—commits any mad act most alienists would ascribe that mad act to the influence of epilepsy and not to a temporary insanity unconnected therewith. My contention is that these "psychic equivalents" point to insanity as a companion disease, and I hope to be able to show that patients who exhibit "psychic equivalents" often become insane, and that ordinary sane epileptics do not show "psychic equivalents" and do not tend to dementia or insanity. That alienists should associate epilepsy with insanity and imbecility and believe in the frequent termination of epilepsy in dementia, was no doubt often justified by the class of cases received by them; but that modern superintendents of colonies should still share such an opinion is the more surprising when we have institutions for sane epileptics. For instance, Dr. W. L. Shanahan, the medical superintendent of Craig Colony, U.S.A., in a lecture says: "*Epilepsy is a disorder leading to dementia.*"[1] This is an opinion not by an "alienist" but by a superintendent of an epileptic colony to which are sent not only many imbecile epileptics but also many sane epileptics; no doubt the degeneracy of the imbeciles may have confused the issue and caught the attention more than the permanence of the sanity of the sane. However this may be, what I am prepared to prove is *that sane epileptics do not tend to dementia to any serious extent.* To do this I have analysed our experience at Maghull, and in order to do so as effectually as possible I have only considered patients who have been under our care for three years and upwards. This excludes all temporary cases and consequently all cases of which the issue is doubtful owing to insufficient time. The numbers available for our purpose are shown in the following table:—

TABLE I.—*Epileptics who have been Inmates of the Homes at Maghull for over Three Years.*

Essential sane epileptics.	Epileptics with "psychic equivalents."	Imbeciles of various degrees.
256	19	84

When we opened our colony we intended to take only sane epileptics, but the natural tendency of parents and guardians at first was to send us only the worst cases, such as imbeciles and troublesome epileptics. As we were undertaking a comparatively new work we had to ascertain how far the colony treatment would benefit the more imbecile cases and how far the troublesome ones would be influenced for their good by the life and peace we offered them. Our staff worked enthusiastically to develop the imbecile and to preserve, and if possible to restore, the balance of the mentally affected, and hence the above divisions of our patients and hence our experience with cases which we did not expect to have, and which we do not now receive for obvious reasons. We do not express opinions, but refer with confidence to Table II., which shows the length of time these patients have been under observation. None of these patients have ever shown "psychic equivalents." Their minds were sane, their conduct rational, although their intellectual capacities varied from clever accomplished individuals to others who might be called feeble minded.

TABLE II.—*Time under Observation of 256 Sane Epileptics.*

No.	Time.	No.	Time.	No.	Time.
61	over 3 years	12	over 10 years	3	over 17 years
29	4	6	11	4	„ 18
26	5 „	10	„ 12	1	19
19	„ 6 „	14	„ 14	1	20
17	7	1	„ 15	3	22
16	„ 8	9	16	1	24
23	9				

Average time under observation nearly 7 years. Only 5 of these patients deteriorated and may be said to have become subjects of dementia:—(1) A woman who had been sent away for dementia 17 years after she became an epileptic; (2) a man who became demented and unmanageable 17 years after he became an epileptic; (3) an emotional girl who became gradually a troublesome dement 23 years after becoming an epileptic; (4) a troublesome girl who became demented 22 years after the onset of epilepsy; (5) a youth who seven years after the onset of epilepsy became demented and quarrelsome. Total dements out of 256 cases 5, or 1.96 per cent. This does not show a strong, or considering the time occupied in the change a rapid tendency to dementia in sane epileptics. Twenty of the 256 were what might be called feeble-minded persons—i.e., persons who possessing all their faculties but without any great mental force, yet were not such as we could apply the term imbecile to. Not one of these deteriorated to any appreciable extent, although they were with us longer than the others and had every opportunity as far as time was concerned to show any impairment in their work or mental condition.

---

[1] Lecture at Fordham University School of Medicine, New York City (International Clinics Series).

Patients with "psychic equivalents of insanity."—The history of these patients tells a very different story. There were 19 patients in this class. Their symptoms varied, and we will refer briefly to the nature of the equivalents which were always periodical: Delusions of poisoning; violent and apparently uncontrollable fits of temper unconnected with attacks; "fits of melancholia"; periodical outbursts of degraded or profane language; periodic efforts to escape by secret and difficult methods when doors were open; sudden, violent, and unprovoked attacks on teachers, nurses, or companions; recurring delusions about religion, &c. To mention two individual cases in detail. One young girl would be amenable to order and discipline for several weeks. She would perhaps be employed in sewing with several others when she would rise deliberately from her place, walk composedly across the room, and pinch a patient so severely as nearly to nip the piece out. She would then resume her seat, and on being taken to task would be very sorry, apologise, and promise amendment, but she repeated the act again and again, and no treatment could affect the impulse. She had to be removed. Another girl, a child about the same age (12 years), would periodically attack the nurses or her companions, pull out their hair or scratch their faces, and, although very sorry in the intervals and very loveable then, no training or warning could prevent their recurrence. Every one of these 22 patients with one exception became worse mentally and had to be removed, although "no stone was left unturned" in our efforts to save them. The majority were afterwards removed by their friends to lunatic asylums. The one exception was an adult woman who had periodical mental attacks, or "psychic equivalents," but who died in "status." Otherwise I have no doubt she would have ended her life in an asylum.

I now regard these not as "psychic equivalents" of epilepsy, but as prodromata or as premonitory symptoms of insanity, and the results—viz., the gradual development of insanity and their final removal to asylums—prove that, practically at least, my view that they are insane is correct. Table III. shows how long and with what success we were enabled for years to keep such cases out of a lunatic asylum, but every case had to be removed finally except one, and she went to her grave instead. It has not often occurred hitherto that we have had such an extended record of patients with "psychic equivalents." Our interest in such cases was always great, but we had no idea until lately that the prognosis was so gloomy. Until I studied these cases I shared the common view of "psychic equivalents" of epilepsy. Since looking up the records I regard "psychic equivalents" as forerunners of insanity.

TABLE III.—*Time in Homes of Patients with "Psychic Equivalents" before Removal became Necessary.*

No.	Time.	No.	Time.	No.	Time.

2	4 ,,	1	11 ,,	1	16 ,,
1	6 ,,	1	13 ,,	1	18 ,,
1	7 ,,				

None of these cases were congenital epileptics.

Alleged causes of epilepsy in those suffering from so-called "psychic equivalents."—In two cases the children were three years of age, and were said to have suffered from sunstroke. In another case the attacks began at three years of age without any cause. In one case, aged 5, the alleged cause was rheumatic fever. Three were 8 years old at the time of the onset of the fits, and in two of them the alleged causes were the extraction of a tooth and a fall. In the remaining 11 cases epilepsy began at from 12 to 18 years of age, and the alleged causes were falls (2 cases), and menstruation (1). No definite causes were alleged in the remainder. In only two cases was there a history of epilepsy or other nervous disease in the family.

TABLE IV.—*The Effects of Time on Imbecile Epileptics.*

Results of Prolonged Treatment of 84 Imbecile Epileptics.

Deteriorated.		Improved or remained *in statu quo.*
53, or 63·8 per cent.	....	31, or 36·8 per cent.

As to our epileptics who were more or less imbecile on their admission to the homes, the above table shows that we have a different tale to tell from that which we have already told about the sane epileptics, but not quite so bad a story as that which we have also told about those cases with "psychic equivalents." These patients when admitted were imbecile to a moderate extent, but all had distinct mental defects. In regard to their habits, they might be said to belong to the better class of imbecile, so that we were able to keep them until they became a nuisance, and the next table shows how slowly the degradation took place. The helpless, hopeless imbeciles were rejected on application, or, if they appeared to be worse than we expected, on being presented for admission they were sent back home as soon as convenient. Those whom we received were taught and trained by enthusiastic officers, and every effort was made to improve their brains and to restrain the violence of the epilepsy.

The degeneration was a gradual process, as the following table (Table V.) proves. This table shows the number of years of their stay in the homes before they became absolutely unsuitable, and there was sometimes great reluctance on all sides to break the bonds that bound the nurses and the patients together.

TABLE V.—*Time 53 Imbecile Epileptics were kept at the Homes before Deterioration Rendered them Quite Unsuitable.*

No.	Time.	No.	Time.	No.	Time.
9	3 years.	4	8 years.	2	14 years.
6	4 ,,	4	9 ,,	3	15 ,,
7	5 ,,	4	11 ,,	1	16 ,,
3	6 ,,	4	13 ,,	1	17 ,,
5	7 ,,				

The next table shows that 31 imbecile epileptics did not degenerate, and gives the time these patients were under observation.

TABLE VI.—*Showing how long 31 Imbecile Epileptics were kept without Deterioration or were Improved by Treatment.*

No.	Time.	No.	Time.
2	3 years (1 still with us)	4	9 years (3 still inmates)
2	4 ,, (both still with us)	1	12 ,, (still an inmate)
5	5 ,, (1 still with us)	1	13 ,, (,, ,,)
4	6 ,, (3 still inmates)	1	16 ,,
3	7 ,, (2 ,, ,,)	1	19 ,, (still an inmate)
7	8 ,, (6 ,, ,,)		

Of these patients 21 are still in the home, several of whom have improved very much, but the majority retain much the same mental conditions as when admitted. None have deteriorated, although the average time under observation was 7·4 years, quite sufficient time for degeneration to set in if epilepsy always lead to dementia.

We have tabulated the ages at which the epilepsy began in all these imbecile cases, so that we might compare them.

TABLE VII.—*Age at which Epilepsy first Appeared in 53 Imbecile Epileptics who Deteriorated.*

No.	Age.	No.	Age.	No.	Age.
12	Birth.	5	7th year.	1	16th year.
2	1st year.	1	8th ,,	1	17th ,,
3	2nd ,,	4	9th ,,	2	18th ,,
5	3rd ,,	2	12th ,,	2	20th ,,
1	4th ,,	1	13th ,,	1	21st ,,
2	5th ,,	1	14th ,,	1	48th ,,
4	6th ,,	2	15th ,,		

In eight cases there was evidence of hereditary disease in the family history.

TABLE VIII.—*Age of Onset of Epilepsy in 31 Cases of Non-deteriorated or Improved Epileptic Imbeciles,*

No.	Age of onset.	No.	Age of onset.	No.	Age of onset.
11	Birth.	2	5th year.	2	9th year.
3	1st year.	1	6th ,,	1	11th ,,
2	3rd ,,	4	7th ,,	1	13th ,,
2	4th ,,	1	8th ,,	1	18th ,,

In 5 of these non-deteriorated cases there was evidence of hereditary disease.

We have not much evidence of the mental condition of the patients before the onset of the epilepsy In one case the child was said to be very bright and precocious in her school accomplishments With the onset of convulsions her knowledge all disappeared, and when she came to us she had to be retaught the days of the week Very slow progress was being made when she died in "status"

In concluding this part of the subject I think it may be considered proved First, that healthy, sane epileptics under the conditions of a normal life in a modern colony do not tend to dementia, and are not liable to so called "psychic equivalents" of epilepsy Secondly, that where "psychic equivalents" occur there is also a tendency to insanity in the future Under the conditions of a normal life the tendency is kept in check, but as time advances, in the great majority of these cases, the tendency becomes stronger and stronger, and most of the cases become unmanageable and drift to an asylum or to the insane wards of a workhouse Thirdly, that imbecile epileptics show a tendency to dementia, 63 per cent of 84 cases becoming demented after being under observation for long periods of time varying from 3 to 17 years, or an average of 7 years On the other hand, 36 per cent. of the 84 cases or 31 imbecile epileptics who were under observation for similar periods of time and under quite similar circumstances, did not change for the better, except in a few instances, after an average period also of 7 years

We have considered the question whether amongst all these patients there were any characteristic differences in the nature of the attacks, the age of onset of the disease, or in hereditary influence, but so far we have not been able to detect any The administration of bromides to imbecile epileptics appears to us to be much more harmful and much more likely to bring about dementia than is its administration to sane cases Again and again, when dementia threatened, we have temporarily arrested its onset by stoppage of all bromides and by attention to the general health

Confusion of ideas in regard to the character of sane epileptics—One writer quotes an authority for saying that the most characteristic phenomenon of epilepsy is not convulsions, but periodical emotional disturbance characterised by sudden depression, or excitability, or fear, home sickness, suicidal desires, and marked mental confusion The same writer also quotes an opinion on the epileptic character as "one compounded of egotism, obstinacy, deceit, hypocrisy, family pride, and reckless, quarrelsome excitability, recurrent outbreaks of temper accompanied by morbid suspicion and wanton destructiveness' Our experience at Maghull, except in the case of the patients with "psychic equivalents," whose character has already been described in this paper, does not lend any support to the truth of the description of the epileptic character just given

The most characteristic phenomena of essential epilepsy are convulsions, and the mental and emotional disturbances are only such as one would expect in a person subject to epilepsy Suppose the reader to imagine himself an epileptic liable to fall down unconscious at any moment and in any place, would he not be likely to suffer from times of depression, excitement or even fear, without such symptoms being considered part of the disease? I do not know what is meant by home sickness but if it refers to institution treatment, it is not more in evidence amongst our patients than amongst boys at a public school Suicidal desires, marked mental confusion, egotism, obstinacy, deceit, hypocrisy, family pride, and reckless or quarrelsome excitability, recurrent outbreaks of temper accompanied by morbid suspicion and wanton destructiveness, are not symptoms at all of simple, essential, sane epileptics I have quoted these supposed characteristics of epilepsy to matrons at Maghull, who have had charge of households containing from 40 to 60 epileptics for many years, and their remarks were not complimentary to the intelligence of the writer who could describe such symptoms as the general characteristics of their past and present inmates Our homes at Maghull are all managed by ladies, and have been so managed since their foundation 24 years ago Were the above statements not a libel on a deserving class, already hopelessly handicapped by one of the most dreadful diseases that afflict humanity, would it be wise or possible to do without the assistance of the sterner sex in dealing with them?

Character of sane epileptics—Ordinary sane epileptics are subject to the same feelings and tempers as other people They are specially dependent on relatives, friends, nurses and attendants owing to their infirmity they are attracted by sympathy and kindness, and are repelled by want of sympathy and unkindness, more so than ordinary individuals They are very responsive to justice and fair play, and appreciate fair dealing acutely, like people to whom it has once been a stranger To appreciate this point we must place ourselves in the epileptic's place and look upon matters from the epileptic's point of view We shall then see that there are many pre epileptic or post-epileptic events which an epileptic strenuously denies knowledge of because he knows nothing of them, does not even know that he has fits, or realise what a fit is He is often surrounded by lies from his childhood upwards through a mistaken notion that any lie that will keep him in ignorance of his epilepsy is justifiable, forgetting that the patient has a brain and soon finds out that he is being deceived and that there is a mystery somewhere which he cannot fathom When he reaches a colony the mystery is solved He neither "dies' nor "goes mad," as ignorant relatives would have us believe he would if he knew the truth about himself, but instead he settles down to make the most of the large portion of life still left to him He recognises his limitations, realises the dangers of his position, and knowing that he is safe in sympathetic company he can enjoy his life when he is relieved of the incubus that preys upon him, and, secure in the company of his equals, the conversation becomes unrestrained and spontaneous, and quite on a level with that of the class of society whence the patients are derived

In conclusion, I would try to impress on the authorities that sane epileptic children can be taught the foundation of all knowledge—viz, reading, writing, and arithmetic—with little more difficulty than with ordinary healthy children Arrangements must be made for the fits, but these only occupy a small portion of their time, and the greater part of it can be utilised for ordinary school work The idea that these children cannot be taught to read, to write, and to do arithmetic, or that it is unnecessary or useless to teach them these things, is a wrong one Education is a therapeutic remedy of great value, it strengthens the brain, tends to develop growing centres, and produces habits of perseverance, of attention, of self control, of initiative, and of determination If the school authorities give out the impression that epileptics cannot be taught, why should we have highly trained and certificated teachers when kind hearted women who know some needle work and some drill would do as well, and the present talent now wasted could be utilised elsewhere?

Epileptics enjoy the pleasure of reading probably as much as other people It was stated in my presence some time ago by the superintendent of an epileptic colony, a colony certainly where a good many feeble minded and more or less imbecile epileptics are admitted, that it is no use teaching epileptics to read that they rarely use the accomplishment or if they do appear to read, they do not absorb the knowledge or even know what they are reading about I have ascertained the facts as regards the same epileptics at Maghull The various matrons gave me the numbers of those who are in the habit of reading books in their leisure hours and who are in the habit of discussing literary questions with each other Amongst 171 male patients, 79 were fond of reading, and occupied their leisure hours in this way Many of the others read spasmodically, but enjoy games and other methods of passing the time better Amongst 140 female patients only 26 were fond of reading, or altogether 105 out of 311, or 33 7 per cent We must remember that the leisure of the women was more likely to be utilised in sewing and embroidery, and where the majority took an interest in such feminine employments it required a strong penchant for a book in the 26 to choose that method for passing the time when, for example, love of dress and other instincts called them instead to the use of the needle Besides, we do not encourage poring over undesirable books and the report of the matrons gives the state of affairs without any desire to vary the records one way or the other of open-air teaching by means of open-air schools, playground classes, and, if possible, the establishment of "night camps"; and the need for systematic and prolonged after-care and following up. An addendum on the care of tuberculous children in Germany is appended to this part of the report, in which an interesting account is given of the work in that country.

The Methods of "Following Up."

The important bearing which the adoption of the proceeding known as "following up" has upon the success of the work of medical inspection and treatment is generally recognised and need not be insisted upon here, but Sir George Newman usefully discusses the methods adopted and indicates the lines along which advance has been made during the year. In the first instance, he notes that this is being partly effected by the larger coöperation of parents, who are invited to be present at the time of the inspection of their children. It has not been found that medical inspection has undermined the sense of responsibility of the parents, but has indeed awakened it. It is true that the mother has only been present from 40 to 60 per cent. of the occasions on which her child was inspected, but Sir George Newman says that there is abundance of evidence in connexion with the results that the apparent slackness is often due to want of opportunity only. So again evidence shows that teachers are coöperating, while the services of the school nurse or health visitor are being increasingly employed. Indeed, efficient following up proves in many areas to be impossible unless the arrangements for the school medical service include the employment of school nurse or health visitor for whole or part time. It is important that their duties should be correlated with that of the attendance officer. Experience has shown, we are told, that the main cause of absence from school is ill-health, and hence the necessity for ascertaining the cause of the ill-health, and also for ensuring the child's return to school as soon as it should properly do so. In this matter the work of the medical officer and the attendance officer comes into close relation. In many districts assistance is given by voluntary agencies and care committees, of the value of which a number of the school medical officers speak favourably.

The Arrangements made for Medical Treatment.

Under the heading "Action Taken by Local Education Authorities in Respect of Medical Treatment," Sir George Newman gives some interesting particulars of their work. Thus we learn that 212 authorities employ school nurses, and 127 of these employ their nurses primarily to assist in the work of inspection. Spectacles have been provided at a cost of from 2*s.* to 3*s.* 6*d.* a pair, the parents often contributing to the cost, but experience has shown that the provision of spectacles is not of itself a sufficient remedy for defects of vision, but that other conditions relating to health, the condition of the home and of the school, its lighting, the size and character of the print of books, must all be taken into consideration. The use of X rays for the treatment of ringworm has increased during the year. Some of the authorities arranged to send the children thus affected to a specialist, others made contributions to hospitals or treatment centres not under their direct control, and others again themselves provided the necessary apparatus. The best results were obtained in Bradford, where of 253 cases treated during the year seven only required a second application. For the purpose of treatment of school children found defective by medical inspection, arrangements were made by some authorities with local hospitals, and these, when found satisfactory, were approved by the Board. It is clear that local education authorities undertaking schemes for medical treatment, whether predominantly "hospital" or predominantly "clinic," should consider: (1) the degree in which the scheme is adequate to the needs of the area; (2) the means taken to secure prompt and continuous attendance at the hospital or clinic without avoidable "leakage," and with satisfactory arrangements for following up; (3) the efficacy and economy of the treatment provided; (4) satisfactory arrangements for after-care, supplementary treatment, and subsequent provision; and (5) the degree in which the treatment scheme is coördinated with the school medical service of the area, particularly in its relation to inspection and re-inspection. The report gives an account in some detail of the arrangements made in London, and shows that, broadly speaking, they are now designed to meet in a substantial degree the above desiderata.

School Clinics.

The next subject to which we desire to refer in our present notice of Sir George Newman's report is that of school clinics. The institution of school clinics is the outcome of routine inspection of children in the schools. The clinic provides a place where a more complete examination can be made of children found or suspected to be suffering from defect of constitution or health, and it may provide a place where this defect is treated. Sir George Newman defines the inspection clinic as "a place for further examination as well as a clearing house," and he tells us that in 1911 there was a great extension of its work, and that "the value of the work of medical inspection in the schools has been much enhanced thereby." He believes that the fuller the development of the inspection clinic the wider is the knowledge of the school medical officers in regard to the medical problems presented by the children of school age, and he says that "the institution of inspection clinics has indirectly led to a large amount of treatment, both of a general and specific character." In support of this view he cites statements in the reports of several school medical officers which tell of their usefulness.

Referring especially to large cities, he says they should be organised in districts, and that no arrangements for the isolated treatment of defects can be considered as satisfactory substitutes for an organisation which, though simple in method, is comprehensive in dealing with the child's needs as a whole. He describes briefly the accommodation which should be provided. No elaborate structure or equipment is needed. Well-lighted rooms, scrupulously clean, are required, providing separate accommodation for children with contagious skin conditions and for differentiation of children who have recovered from infectious disease. He points out that in most areas there is perhaps the greatest need for the treatment of minor ailments, including under this description the common forms of skin disease, such as sores of all kinds, impetigo, scabies, pediculosis, ringworm, cuts, and bruises; external eye diseases, such as blepharitis and conjunctivitis, and discharge from the ears. This list of maladies, which we have quoted from Sir George Newman's report, would give ample material for a clinic related to any considerable population. That the list may be largely extended is obvious. Question arises by whom it should be officered. Sir George Newman considers that while the supervision and control of the medical work should be in the hands of the school medical officer, the actual work of treatment can be undertaken either by members of a whole-time medical staff of the authority or by part-time practitioners specially appointed for the purpose. The experience derived from general practice affords a better basis for the work of treatment in a school clinic than any other, and it is certain to our mind that development should take place along this line. The circumstances of some areas have to be specially considered, and some of the maladies which have to be treated may require particular provision, but for the greater proportion of the maladies which require medical aid there must be advantage in employing the services of medical practitioners in the district. Sir George Newman gives no dissent from the employment of the general medical practitioner; indeed, we think we may say that the Board of Education evidently recognises the advantages which attach to the adoption of this method of officering the school treatment clinic. Particulars are given in the report of the arrangements made in a few treatment centres. Thus we learn that in Abertillery the work is carried out by the school medical officer; in Bradford it is undertaken by the whole-time medical staff of the authority. In Wandsworth the treatment centre belongs to local medical practitioners, and two surgeons have been appointed to undertake the eye cases, while three surgeons have been attached to the aural department, and each surgeon operates once a fortnight. Dental treatment appears to be included among the branches of work in several school clinics at the present time.

The Work of the School Medical Officer.

Perhaps some of the most important of the pages in Sir George Newman's report are those in which he introduces a discussion of the physical condition of school children. He appeals very forcibly to school medical officers to appreciate in its true relation the nature of the work upon which they are engaged, and insists *upon* the value of their work depending upon their ability to detect the beginnings of disease It is necessary, he says, that under present circumstances their attention should be directed to the detection and amelioration of gross defects, but it is important that they should also consider disease in its earliest and less recognised aspects This, no doubt, requires considerable skill and experience, but it is of the first importance, and Sir George Newman properly claims that no considerations of the alleged monotony of [illegible] or of the greater importance o [illegible] scheme, or of the inadequacy [illegible] as reasonable excuse for indifferent or slovenly work He claims that what is needed is not only a higher degree of clinical study and investigation, but a more thorough appreciation of disease as a crippling agency, and he gives [illegible] upon the school medical officer's professional work and upon his capacity as a practical administrator, *the professional* work calls for imagination as well as clinical ability, exact observation, and experience the school doctor learning to understand much more fully than hitherto the sequelæ of *even minor morbid conditions*, the administrative work demands a wide knowledge of the circumstances of the case and of what is expedient, practicable, and reasonable in the way of remedy and prevention For work in both directions better professional *training, greater skill and knowledge are* available than some years ago, and no one can doubt the devotion of the younger members of the medical profession upon whom the duties mainly devolve We have no hesitation in saying *confidently that the care and clinical skill demanded* by Sir George Newman will be forthcoming

THE HEALTH OF THE NAVY IN 1911

Continued Improvement in Health

THE strength of the Royal Navy in the year 1911 amounted to 117,100, of which number 79,520 were serving in the Home Fleet or on the Home Station, the remaining 37,580 being distributed in the seven fleets and squadrons serving abroad The health *of the naval force as* a whole shows a continuous improvement as compared with the average of the preceding five years, 1906–10 Thus, the number of cases of sickness has decreased from 679 9 per 1000 strength to 652 9, *the daily sick from* 28 07 to 27 07, the deaths from 3 35 to 3 12, and the invaliding from 16 44 to 15 94 It is true that these reductions are not very pronounced, neither is the improvement general throughout the entire force But for the men serving in the Home Fleet and Home Station, forming about two-thirds of the whole, there is an improvement in every item, except in the daily sick ratio for the latter, and the invaliding ratio for the former, which have increased to a very slight extent The highest admission ratio, 876 per 1000, occurred on the East Indies Station, but this was much below the five year average (1040), the deaths on this station (10 per 1000) were, however, in excess of the average (8·76) The highest ratio of daily sick, amounting to 40 32 per 1000, was, as usual, among men of the Irregular List, including crews on passage to and from foreign stations and on the west coast of America Next comes the Home Station, with a daily average of 35 85, while the healthiest command was that of North America and the West Indies, with a ratio of 19 84 The Home Fleet had, as usual, a much lower sick rate, 23 36, than the men on the Home Station just mentioned the latter body including depôts and training ships, the hospitals at home, and the Royal Naval College at Greenwich

The chief causes of admission to hospital were venereal affections, amounting *to 115 per 1000 of strength* This shows but slight improvement on the average ratio for 1906–10, which was 121 The daily sick from this cause numbered 7 21 per 1000, which is rather better than the quinquennial *ratio of 8 01 The group of digestive diseases,* with 114 per 1000 admissions, came next Tuberculosis (2 44 cases per 1000) was slightly above the previous average of 2 02, and rheumatic fever with 7 61 was also higher than the average (5 83) On the other hand, pneumonia (3 88) and malaria (3 52) were less prevalent, and Mediterranean fever, with 6 admissions throughout the whole navy, was practically absent The most fatal disease was tuberculosis, causing 38 deaths (0 32 per 1000), after which came enteric fever and pneumonia, each with 30 deaths (0 25 per 1000) and organic heart disease with 29 deaths Enteric fever and tuberculosis were slightly more fatal than during the previous quinquennium The chief causes of invaliding were heart disease (2 50), nervous diseases (2 40), and tuberculosis (2 02 per 1000) None of these ratios are reductions on the previous average

On comparing the figures of the different naval commands we find, as already mentioned, that the East Indies Station suffered most from sickness, the force having an admission ratio of 876 per 1000, with 36 [illegible] deaths Malaria caused 70 4 [illegible] 28 7, the other chief cause [illegible] diseases and affections of the skin and connective tissue The healthiest commands were the North American and West Indies Station with 565 8, and the Home Fleet with 569 1 *admissions per 1000*

Prevalence of Chief Diseases

The most important diseases may now be considered in *regard to their prevalence* and distribution *Influenza* caused less sickness (1364 cases) than has been usual of late years, the admission ratio being 11 64, compared with 24 46 in the previous quinquennium There were 2 deaths *Cases occurred in all the commands (except the Cape),* but it was mostly of a mild type There were 172 cases of *diphtheria*, of which 155 were admitted on the Home Station, the type must have been very mild, as not a *single case was fatal* Of *these cases* 116 *occurred at the* Shotley training establishment in the autumn, the disease prevailed somewhat in the neighbourhood of the depôt, and throughout Suffolk generally There was also some prevalence *at Devonport among the civil population during the latter* part of the year, when 20 cases were admitted on the *Impregnable*

Enteric fever caused 137 admissions and 30 deaths, the only outbreak in which a sequence of cases occurred was on board the *Argyll*, belonging to the Atlantic Fleet, but stationed in home waters, careful inquiry led to the conclusion that in all the seven cases infection was contracted when on leave ashore Plymouth being held responsible for four cases *Mediterranean fever* is now practically extinct in the navy; there were only six admissions during the whole year One of these, in the Home Fleet, was of doubtful diagnosis, the remaining five were on the Mediterranean station, three being Englishmen and two Maltese The two latter "had presumably both drunk unboiled goats' milk at their homes", one of the other cases acknowledged to have done so at his home in Malta one month before admission *Pneumonia* caused 3 88 admissions and 0 25 death per 1000, compared with the quinquennial averages of 4 41 and 0 34 respectively A series of 14 cases, epidemic in character, occurred on the *Bellerophon* between Feb 14th and March 5th, while serving in the Home Fleet, though it is not stated where she was stationed The cases were characterised by early and marked cardiac depression, with a tendency to cerebral symptoms

Malaria was much less prevalent in 1911 than has been the case recently, the admissions were in a ratio of 3 52 per 1000, compared with 5 03, the quinquennial average *On the* East Indies Station the cases were *70 43* per 1000, compared with 142 4 the preceding quinquennial ratio, many of the cases were recurrent attacks of previous infection contracted in the Persian Gulf, there was little fever at Bombay *A series of 45 cases of malaria occurred* among landing parties from the *Brilliant* and *Melpomene* during the revolution in Honduras in January, mostly of the malignant tertian variety On the other hand, a party of 52 officers and men were landed for duty and exposed to infection in a very malarious country for three weeks Quinine was given prophylactically, and mosquito nets used the whole party escaped scot free *Tuberculosis* caused 286 admissions and 38 deaths, giving ratios of 2 44 and 0 32 per 1000, slightly below the quinquennial ratio, the sick berth staff, with 6 82 per 1000 admissions, and ship s cooks, with a ratio of 5 52, suffered much more than the others, for seaman ratings the admissions were 2·4 per 1000. *Venereal diseases*, as already mentioned, showed some, though slight, improvement on recent years; chancroid and gonorrhœa admissions, with ratios of 20 and 64 per 1000 respectively, are indeed slightly in excess of the quinquennial average; and secondary syphilis (25·2) is but very slightly less than the average (28·9), but the primary disease, with 5·61 cases per 1000, and 0·23 daily sick, has been much less frequent than hitherto. The quinquennial ratios were 10·79 and 0·78 respectively. The invaliding ratio (0·52) has also diminished compared with the previous average (0·94).

Only 83 cases of alcoholism were admitted from the whole force of 117,100. This works out at 0·7 case per 1000, a substantial reduction on the five-year average of 0·96. There were 218 cases of poisoning, of which 150 were due to ptomaines, a large increase over recent years, and 2 deaths resulted from this cause; 30 cases were caused by eating periwinkles obtained from beds in the Medway On board the *London*, of the Atlantic Fleet, there were 3 cases, 1 fatal, after eating fish cakes and tinned peas; 14 cases on the *Fantome*, of the Australian Station, were attributed to prawns; and 14 men on the *Pyramus*, of the same station, were attacked five hours after eating a meal of corned beef (not tinned).

The appendix contains a paper by Fleet-Surgeon P. W. Bassett-Smith on the Serum Diagnosis Test for Syphilis, and three other communications of professional interest.

ASYLUM REPORTS.

Report of the Inspector-General of the Insane of New South Wales for the Year 1911.—The largest number of patients yet recorded was admitted for treatment at the various hospitals of New South Wales. The number of admissions during the year was 1247, of whom 1061 were admitted for the first time. The increase is, in part, explained by the increase of the population in the State, but is somewhat greater than this alone would account for. The number of patients discharged recovered was 459, equal to a rate of 36·81 per cent. on the admissions and readmissions. In this return, however, are included the figures from the Hospital for Imbeciles at Newcastle. Excluding Newcastle, the recovery rate is 37·35 per cent. The number of deaths was 485, giving a percentage of 8·06 on the average number resident. The chief causes of death were general paralysis, general diseases of the brain, epilepsy and convulsions, and diseases of the lungs. It appears that for some time there has been a growing need for alteration in some parts of the Lunacy Act. The most pressing points requiring alteration appear to be provisions for defining the powers conferred by the Act in regard to the control of insane patients outside hospitals for the insane and licensed institutions and provision for the admission of voluntary patients to hospitals for the insane and licensed houses. A number of patients who are aware of their mental condition go to the hospitals seeking admission as ordinary patients. In many cases the illness is not sufficiently advanced to require certification, and in others the patient or his friends resent certification. At present there is no provision in the Act to permit of the admission of such patients, and in consequence they have to remain without treatment until their cases are further developed, with the result that curable conditions sometimes pass into those that are incurable. Provision is further required for placing on a proper footing the manner in which insane patients may be continued under care in private houses.

Mental Hospital of the City of Cardiff (Annual Report for the year 1911.)—The average daily number resident during the year was 697. There were admitted 232 patients, as against 208 patients during the previous year. The discharges numbered 166, and of these 105 were discharged recovered, the recovery rate being 60 per cent., a very remarkable one. Dr. Edwin Goodall, the medical superintendent, has looked through the recovery rates of 63 asylums since their opening. He finds a recovery rate of 60 per cent. only reached three times, and a rate from 50 per cent. to 60 per cent. 14 times. He regards such abnormally high rates in institutions compelled to receive all cases as due mainly to some unusually favourable circumstance, or combination of circumstances, not under control; and only to a lesser extent to treatment. Nearly 64 per cent. of the patients were in residence for not more than eight months. The deaths numbered 77, or 12·2 per cent. and 9·9 per cent. of males and females respectively. Post-mortem examinations were held in 72 of the deaths. A further extension of the physiological and pathological departments is contemplated, and Dr. Goodall appends to his report interesting abstracts of the research work during 1911 by himself and his colleagues.

Annual Report on Certification of Lunatics and Observation Wards, 1911–12 (by Mr. John Carswell, certifying physician in lunacy to the Glasgow parish council).—The parish of Glasgow has a population of 579,000. It is the statutory duty of the parish council to make provision for the medical examination of supposed lunatics, for the removal to asylums of persons certified to be insane, and for the maintenance of patients in asylums. When intimation is received by the inspector of poor that a person is in need of attention on account of mental disorder he immediately notifies the certifying physician in lunacy, who forthwith visits the patient. After medical examination the patient is removed by the inspector's assistants either to the observation wards or to the asylum, as the medical officer advises. Patients removed to the observation wards are not placed under any certificate implying insanity, and they are under no compulsion to go to the observation wards. During the year which ended on May 15th, 1912, there were dealt with 1138 cases. Of these, 333 were certified and removed directly from their homes to the asylum; 242 were treated for a time in the observation wards and subsequently certified; and 454 patients were treated in the observation wards and were subsequently discharged recovered or improved or died. The types of cases which are regarded as qualifying for admission to the observation wards are: (*a*) Where the mental symptoms are a sequel or accompaniment of diseases that in ordinary circumstances terminate within a definite time. (*b*) Where, although the mental symptoms would seem to indicate lunacy, the medical officer is of opinion that such symptoms are likely to be of short duration. (*c*) Where the patient's mental state gives rise to apprehension, but where the symptoms are not sufficiently marked to enable the certifying physician to affirm either sanity or insanity. (*d*) Where the mental disorder is associated with alcoholic abuse. (*e*) Senile cases where there are temporary symptoms of mental derangement, which make it undesirable that the patients should be treated in a general hospital ward. Indeed, the main object of the hospital is to provide a probationary curative hospital for incipient and recoverable forms of mental disorder. We wish there was a greater tendency to follow the excellent example set by the Glasgow Parish Council.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Meeting of the Council.

A quarterly meeting of the Council was held on Jan. 9th, Sir Rickman J. Godlee, the President, being in the chair.

The best thanks of the Council were given to Mr. Harold Peake for his gift of a collection of skulls and skeletons of Anglo-Saxons of the seventh century, found near Newbury.

The best thanks of the Council were given to Mr. H. E. Juler, F.R.C.S., for presenting 150 specimens illustrating diseases and injuries of the eye. The best thanks of the Council were also given to Dr. T. Colcott Fox for presenting a series of cultures of fungi associated with diseases of the skin.

In response to a request from Sir Henry A. Miers it was resolved to place the lecture theatre at the disposal of Mr. F. W. Twort, superintendent of the Brown Institution, for a course of five lectures on Jöhne's disease.

The following resolutions received from a special committee of the Council were adopted:—

1. That the general hospitals with medical schools be advised each to [illegible] for tuberculosis, such department to form part [illegible] the hospital.

[illegible] with medical schools should consider the advisability of applying for provisional "approval" as regards sanatorium benefit.

3. That in localities where it is possible the services of consulting physicians and surgeons should be utilised for consultation in cases of tuberculosis under the Insurance Act.

VITAL STATISTICS

VITAL STATISTICS FOR 1912.

The following statement shows the birth- and death-rates and the rates of infantile mortality in England and Wales and in certain parts of the country during the year 1912, the figures being provisional:—

—	Annual rates per 1000 living.			Deaths under one year to 1000 births.
	Births.	Deaths.		
		Crude	Corrected.*	
England and Wales	23·8	13·3	13·3	95
95 large towns, including London	24·9	13·8	14·6	101
146 smaller towns	23·8	12·4	13·0	99
England and Wales less the 241 towns	22·6	12·9	12·1	86
London...	24·7	13·3	14·3	90

* The corrected death-rates are the rates which would have been recorded had the age and sex constitution of the populations of the several areas been identical with that of England and Wales as [illegible] ns applied to the crude rates have [illegible] nstitution of the populations of the [illegible] are, therefore, only approximately

The figures relating to London have been added since 1910. It will be noted that the statistics now deal with 95 great and 146 smaller towns, instead of *with 77 great towns and* 136 smaller, as in previous years. The birth-rates and death-rates have alike decreased in every section save one—the birth-rate in the smaller towns shows a fractional increase.

HEALTH OF ENGLISH TOWNS.

IN the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census, and whose aggregate population at the middle of this year is estimated at 17,852,764 persons, 8305 births and 5657 deaths were registered during the week ended Saturday, Jan. 18th. The annual rate of mortality in the 95 or 96 towns, which had been 15·1, 15·7, and 15·4 per 1000 in the three preceding weeks, rose to 16·5 per 1000 in the week under notice. During the first three weeks of the current quarter the mean annual death-rate in these large towns averaged 15·9 per 1000, against 16·0 in London during the same period. The death-rates in the several towns ranged from 7·5 in Tottenham, 8·6 in Gillingham, 8·9 in Darlington, 9·0 in Wimbledon, and 9·1 in Great Yarmouth, to 23·8 in Carlisle and in Aberdare, 24·1 in Ipswich and in Wigan, 27·3 in Dudley, 27·5 in Rotherham, and 27·6 in West Hartlepool.

The 5657 deaths from all causes in the 96 towns were 372 in excess of the number in the previous week, and included 526 which were referred to the principal epidemic diseases, against 520 and 506 in the two preceding weeks. Of these 526 deaths, 277 resulted from measles, 87 from infantile diarrhœal diseases, 61 from whooping-cough, 59 from diphtheria, 25 from scarlet fever, and 17 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·5 per 1000, and coincided with the rate in each of the two preceding weeks. The deaths attributed to measles, which had declined from 336 to 268 in the three preceding weeks, slightly rose to 277 last week, and caused the highest annual death-rates of 3·8 in Sheffield, 4·0 in Swindon, in Barrow-in-Furness, and in Stockton-on-Tees, 4·2 in St. Helens, 4·4 in Preston, 4·6 in Wigan, 5·3 in Edmonton, and 6·1 in South Shields. The deaths of infants under 2 years of age referred to diarrhœa and enteritis, which had been 65, 78, and 72 in the three preceding weeks, rose to 87 last week, and included 31 in London, 6 in Liverpool, 5 in Stoke-on-Trent, 5 in Manchester, and 3 in West Ham. The fatal cases of whooping-cough, which had declined from 64 to 55 in the four preceding weeks, rose to 61 last week; 16 deaths were recorded in London, 5 in Liverpool, 4 in Blackburn, and 3 in Rotherham. The deaths attributed to diphtheria, which had been 52, 42, and 64 in the three preceding weeks, fell to 59 last week, and included 9 in London, 6 in Portsmouth, 4 in Liverpool, 4 in Manchester, and 3 in Leeds. The deaths referred to scarlet fever, which had increased from 21 to 32 in the three preceding weeks, declined to 25 last week, of which number 9 were registered in London and 7 in Birmingham. The fatal cases of enteric fever, which had risen from 9 to 15 in the *four preceding weeks, further rose to* 17 last week, and included 3 in London, and 2 each in Birmingham, in Manchester, and in Salford.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospitals, which had been 2112, 1954, and 1889 at the end of the three preceding weeks, had further declined to 1828 on Saturday last; 204 new cases of this disease were admitted to these [illegible] 191, 170, and 202 in the [illegible] itals also contained on [illegible] 810 of measles, 257 of [illegible] fever, but not one of [illegible] all causes in London were 103 in excess of the number in the previous week, and were equal to an annual death-rate of 16·5 per 1000. The deaths resulting from diseases of the respiratory system, which had steadily risen from 285 to 311 in the four preceding weeks, further rose to 353 last week, and were 50 above the number recorded in the corresponding week of last year.

Of the 5657 deaths from all causes in the 96 towns last week, 165 resulted from various forms of violence and 446 were the subject of coroners' inquests. The causes of 63, or 1·1 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified last week in Manchester, Leeds, Bristol, Bradford, Newcastle-on-Tyne, Nottingham, Portsmouth, Salford, and in 60 other smaller towns. The 63 uncertified causes of death included 11 in Liverpool, 6 in Birmingham, 4 in St. Helens, 4 in Gateshead, and 3 each in London, in Bootle, in Southport, in Preston, and in Carlisle.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns, with an aggregate population estimated at 2,259,400 persons at the middle of this year, 1211 births and 802 deaths were registered during the week ended Saturday, Jan. 18th. The annual rate of mortality in these towns, which had been 17·1, 17·6, and 17·3 per 1000 in the three preceding weeks, rose to 18·5 per 1000 in the week under notice. During the first three weeks of the current quarter the mean annual death-rate in the Scotch towns averaged 17·8, or 1·9 per 1000 above the rate which was recorded in the 96 large English towns during the same period. Among the several Scotch towns the death-rates last week ranged from 13·5 in Hamilton and in Kilmarnock, 15·3 in Motherwell, and 16·1 in Falkirk, to 20·7 in Paisley, 25·5 in Greenock, and 27·5 in Ayr.

The 802 deaths from all causes were 54 in excess of the number in the previous week, and included 64 which were referred to the principal epidemic diseases, against 66 and 57 in the two preceding weeks. Of these 64 deaths, 36 resulted from whooping-cough, 10 from diphtheria, 10 from infantile diarrhœal diseases, 5 from scarlet fever, 2 from enteric fever, and 1 from measles, but not one from small-pox. These 64 deaths from the principal epidemic diseases were equal to an annual death-rate of 1 5 per 1000, and coincided with the rate in the 96 large English towns. The deaths attributed to whooping-cough, which had been 18, 29, and 30 in the three preceding weeks, further rose to 36 last week, and included 26 in Glasgow and 3 in Leith. The deaths referred to diphtheria, which had been 5, 13, and 10 in the three preceding weeks, were again 10 last week, of which number 7 occurred in Glasgow. The fatal cases of diarrhœa and enteritis (among infants under two years of age), which had been 8, 11, and 7 in the three preceding weeks, rose to 10 last week, and comprised 5 in Dundee, 4 in Glasgow, and 1 in Kilmarnock. The 5 deaths attributed to scarlet fever, of which 4 were recorded in Glasgow and 1 in Dundee, were equal to the average in the four preceding weeks. The 2 fatal cases of enteric fever were registered in Aberdeen and Clydebank respectively, and that of measles in Falkirk.

The deaths referred to diseases of the [illegible] system conclusion, it may be stated that the aggregate mortality in London during December from the principal infectious diseases, excluding diarrhœa, was 31·5 per cent. above the average.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet Surgeon: J. McElwee to the *Carnarvon*, on transfer of flag. Staff Surgeons: T. H. Vickers to the *Blanche*, on recommissioning; N. B. V. Jacob to the *Vivid*, additional, on transfer of flag; F. Bolster to the *King Alfred*, on transfer of flag, and to the *Hecla;* and A. J. Sheldon to the *Philomel*. Surgeon: W. L. Cowardin to the *Carnarvon*, on transfer of flag.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Edwin Eckersley, from supernumerary, is restored to the establishment, vice G. Wilson, retired (dated Jan. 20th, 1913).

Surgeon-General L. E. Anderson has arrived home for duty from India on transfer to the Home Establishment.

Colonel R. Kirkpatrick, C.M.G., Assistant Director of Medical Services at Bloemfontein, South African Command, has been placed under orders for transfer to India. Colonel A. E. Tate has taken up duty at Allahabad as Assistant Director of Medical Services to the Allahabad and Fyzabad Brigades of the Eighth (Lucknow) Division.

Lieutenant-Colonel J. S. Green, on return home from a tour of service in India, has been appointed to the Irish Command for duty. Lieutenant-Colonel H. J. Fletcher has been transferred from Abbottabad to Sialkot and appointed to hold charge of the Military Hospital. Lieutenant-Colonel Sir W. B. Leishman has been selected for appointment as Honorary Physician to His Majesty the King in succession to Surgeon-General G. D. Bourke, C.B., retired. Lieutenant-Colonel B. Forde, in charge of the Detention Hospital at Deepcut, Aldershot Command, has been placed under orders for transfer to Salisbury Plain District to hold charge of the Military Hospital at Bulford Camp in succession to Lieutenant-Colonel C. W. Johnson. Lieutenant-Colonel H. E. Cree has taken over charge of the Cantonment Hospital at Subathu, Simla Hill District, Third (Lahore) Division.

Major G. J. S. Archer has been appointed for duty to the Southern Command on transfer to the Home Establishment by exchange from Burma. Major H. M. Nicholls, in charge of the Military Hospital at Deolali, has been granted six months' leave of absence home from India. Major T. B. Unwin has been transferred from the London District to Caterham and appointed to hold charge of the Military Hospital. Major E. W. Powell has taken up duty at Ballincollig on transfer from Kilworth. Major F. W. Begbie has been selected by H.E. the Commander-in-Chief in India for appointment as Specialist in Advanced Operative Surgery to the Fifth (Mhow) Division. Major R. B. Black has arrived home on leave of absence from Egypt. Major D. J. Collins, Specialist Sanitary Officer to the Dublin District, has embarked for a tour of service in India. Major C. W. H. Whitestone, Deputy Assistant Director of Medical Services for Mobilisation in the First (Peshawar) Division, has been transferred from Cherat to Peshawar. Major A. D. Waring, on return home for duty from Hong-Kong, has been appointed to the Southern Command for duty. Major W. J. Taylor has been transferred from the Military Hospital at Colchester to Bedford, and appointed to officiate in charge of the Military Hospital and Recruiting Medical Officer at the Depôt of the Bedfordshire Regiment during the absence on leave of Lieutenant-Colonel G. F. Poynder. Major A. C. Fox has been transferred from the Military Hospital at the Curragh Camp, Kildare, to Dublin. Major E. Brodribb has taken up duty at the Military Hospital, Dover, on transfer from Shorncliffe.

Captain R. J. Franklin, in medical charge at Fort Camden, Queenstown, Cork District, has been placed under orders for service in India. Captain F. W. Lambelle, specialist in advanced operative surgery to the Fifth (Mhow) Division, has been appointed for duty to the Station Hospital at Maymyo, Upper Burma, on permanent transfer. Captain C. R. M. Morris, on return from a tour of duty at Sialkot, has been appointed to the Southern Command. Captain G. F. Rudkin, staff surgeon at Fort St. George, Madras, and medical officer to H.E. the Governor's Body Guard, has been granted eight months' general leave of absence home from India. Captain J. W. S. Seccombe has been transferred from the Military Hospital at Devonport to Taunton for duty. Captain A. L. Foster has joined the Military Hospital at Rawal Pindi on transfer from Kalabagh Cantonment, Murree Hill District. Captain M. P. Leahy, medical officer to the Ordnance Establishment and Section Hospital at Kirkee, has arrived home on six months' leave of absence from India. Captain C. Pyley has embarked for a tour of duty at Bermuda. Captain G. De la Cour has been placed under orders to join the Irish Command, and on arrival will be appointed to the Dublin District for duty. Captain J. E. H. Gatt has been transferred from the Military Hospital at Benares to Cawnpore Cantonment for duty. Captain F. W. M. Cunningham has joined the Station Hospital at Kuldana, Murree Hill District, on transfer from Rawal Pindi Cantonment. The following officers have joined the Royal Army Medical College, Grosvenor-road, S.W., for the promotion courses from the rank of Captain to that of Major:—Captains W. C. Nimmo (from Chatham), M. Keane (Colchester), C. F. White (Portland), F. C. Sampson (Barry Camp), T. S. Blackwell (Athlone), P. J. Marett (Gravesend), A. D. O'Carroll (Bulford Camp), W. C. Smales (Poona), T. C. C. Leslie (Youghal), and H. M. J. Perry (Woolwich).

Lieutenant J. M. Weddell, on arrival in India from the London District, has been appointed to the Eighth (Lucknow) Division. Lieutenant C. H. Stringer has been transferred from Rollestone Camp, Salisbury Plain, to the Royal Victoria Hospital, Netley. Lieutenant L. C. Hayes has left the London District for duty in Bermuda. Lieutenant V. P. Hutchinson, on arrival in the South African Command, has been attached to the Military Hospital at Pretoria. Lieutenant P. A. With has been transferred from the Military Hospital at the Curragh Camp to Kilbride. Lieutenant E. G. S. Cane, at present stationed at Dublin, has been placed under orders to embark for service in India.

INDIAN MEDICAL SERVICE.

Colonel H. St. Clair Carruthers, Inspector-General of Civil Hospitals in Burma, has arrived home on eight months' combined leave of absence from Burma. Colonel B. B. Grayfoot has taken up duty as Assistant Director of Medical Services to the Derajat and Bannu Brigades of the Eighth (Lucknow) Division.

Lieutenant-Colonel S. H. Henderson, Officiating Inspector-General of Prisons in the United Provinces, has arrived home on 13 months' leave of absence from India. Lieutenant-Colonel D. T. Lane has taken up duty as Civil Surgeon at Ambala on return from leave of absence. Lieutenant-Colonel A. R. S. Anderson has been selected to officiate as Civil Surgeon at Dacca, in succession to Lieutenant-Colonel E. A. Hall, granted furlough.

Major T. H. Foulkes has been selected by the Foreign Department for appointment as Physician to the Mysore Durbar. Major P. St. C. More has taken up duty as Civil Surgeon at Sialkot on return from leave of absence. Major E. J. O'Meara has been selected for appointment as a Fellow of the Allahabad University. Major J. G. G. Swan, civil surgeon at Dalhousie, has been placed under orders for transfer to Jullundur for appointment as Civil Surgeon. Major J. W. Lethbridge has been granted 15 months' leave of absence home from India by the Foreign Department. Major C. F. Weinman, civil surgeon at Dinajpur, has been granted furlough. His Majesty the King has been graciously pleased to appoint Major James Davidson to be a Companion of the Distinguished Service Order (D.S.O.) in recognition of his services in connexion with the military operations against the Abors on the North-Eastern Frontier of India. Major W. H. Tucker has taken up duty as Physician to the Travancore Durbar under the Foreign Department. Major G. Bidie has been granted six months' extension of his leave of absence home from India on medical certificate.

The Chief Commissioner of the Central Provinces has been pleased to appoint Captain E. P. Wernicke, officiating civil surgeon at Hoshangabad, to the executive and medical charge of the Hoshangabad District Jail. Captain F. P.

Mackie has been placed upon special duty under the orders of the Director-General of the Indian Medical Service. Captain K. S. Singh, on return to duty from leave of absence, has been appointed Plague Medical Officer at Amritsar. Captain J. J. Robb has been granted combined and study leave of absence for one year and 14 days home from India. Captain A. W. Hewlett, officiating superintendent at the Central Prison, Agra, has been placed on special duty, under the orders of the Government of India. Captain F. H. Salisbury has taken up charge as Superintendent of the Central Jail at Dacca, in succession to Major E. R. Parry. Captain C. A. F. Hingston has arrived home on leave of absence from India. Captain W. T. McCowen has been promoted to the brevet rank of Major, in recognition of his gallant services during an attack on a squadron of his regiment in Persia. Captain J. McPherson has been selected by the Foreign Department for appointment as Medical Officer in charge of the Mewar Bhil Corps. Captain P. M. Rennie has been granted an extension of leave of absence for five months for study purposes. Captain H. B. Scott has been appointed to officiate as Resident Medical Officer in the General Hospital, Rangoon, in succession to Captain S. T. Crump, granted leave of absence. Captain E. C. Taylor, officiating agency surgeon of the second class, has been deputed to the Central Research Institute at Kasauli for special duty in the Bacteriological Department. Captain L. Reynolds and Captain E. S. Phipson have arrived home on leave of absence from India. The services of Captain A. J. H. Russell have been placed temporarily at the disposal of the Government of Madras Presidency. Captain H. Watts, officiating civil surgeon at Betul, has been appointed to the Executive and Medical Charge of the Betul District Jail. The services of Captain A. S. Leslie, superintendent of the Central Jail at Rangoon, Lower Burma, have been replaced at the disposal of the Home Department of the Government of India.

H.E. the Commander-in-Chief in India has appointed Lieutenant G. Tate to be Specialist in Midwifery and Diseases of Women and Children to the Fifth (Mhow) Division of the Southern Army.

Territorial Force.

Royal Army Medical Corps.

1st Home Counties Field Ambulance, Royal Army Medical Corps: Duncan Matheson Johnston to be Lieutenant (dated Jan. 18th, 1913).

3rd Scottish General Hospital, Royal Army Medical Corps: Major Thomas K. Dalziel to be Lieutenant-Colonel (dated Dec. 16th, 1912). Captain William MacLennan to be Major (dated Dec. 16th, 1912)

2nd Western General Hospital, Royal Army Medical Corps: The undermentioned officers resign their commissions (dated Jan. 22nd, 1913):—Major Edmund T. Milner, Major Judson S. Bury, and Captain James L. Smith. The undermentioned Captains to be Majors (dated Jan. 22nd, 1913):—Arthur H. Burgess, John H. Ray, and George R. Murray.

Attached to Units other than Medical Units.—Lieutenant John Tait to be Captain (dated Dec. 30th, 1912). Lieutenant Thomas N. Thomas to be Captain (dated Dec. 17th, 1912). Lieutenant William H. Newton resigns his commision (dated Jan. 18th, 1913.) Lieutenant Joseph B. Dawson resigns his commission (dated Jan. 22nd, 1913).

For attachment to Units other than Medical Units.—Frank Clayton to be Lieutenant (dated Nov. 18th, 1912.)

Archiv für Schiffs- und Tropen-Hygiene.

In the *Archiv fur Schiffs- und Tropen-Hygiene* Dr. L. Külz has described a myositis purulenta tropica or abscess amongst the muscles, which he ascribes to filaria loa. He has frequently met it in Cameroon, and has himself suffered from it, we are sorry to note. The disease begins with slight pain ascribed to an accident or to a chill, and thought to be rheumatic, but soon becomes serious. Still the patient does his work with little feeling of illness and is surprised to find that his temperature is raised. There are deep tenderness on pressi [illegible] edges, increased faradic [illegible] and leucocytosis. The [illegible] suppurates. The abscess should be opened without waiting *for it to point; if it remain unopened* the pus will burrow and the patient will waste. The first abscess is in the limbs, but never on face, neck, hands, or feet; the secondary abscesses occur anywhere in the muscles. Lymphatic infection is rare. The disease is more common and the abscesses more numerous in natives than in Europeans. Children are not attacked. The treatment is free incision (the pus often bursts out with surprising force and quantity), and then drainage. The wounds heal quickly. Dr. Külz marks the most tender spot and makes his incision over that. Yet it is sometimes difficult to find the focus, hence exploratory puncture is little help. A filaria was once found in an exploratory puncture. The disease occurs in the area of distribution of filaria loa; all the patients had microfilaria diurna in their blood, and some had a history of filaria loa. That is why children who are not attacked by this filaria do not suffer from these abscesses, and the greater severity of the disease in natives than in Europeans is also thus explained. Dr. Külz then states the damage done by filaria loa: (1) filarial œdemas; (2) its presence on the eye; (3) it infects the blood with microfilaria diurna; (4) dying it becomes a foreign body in the muscles and causes tropical muscle abscesses. In the same number Staff-Surgeon Dr. Jaeger gives a very complete account of the demography of the Ebolowa district in South Cameroon. He has evidently won the confidence of the natives, who, in a pleasant fruitful land, numbered some 6000. Of 635 men examined 20 per cent. had gonorrhœa and 3·5 per cent. had chancres. The women used to have on an average 4½ children, but that number is decreasing, partly by abortion, partly perhaps in consequence of prostitution. The infantile mortality is 165. Prominent diseases are malaria, yaws, and intestinal parasites. He suggests that the frequency of yaws may explain the relatively small severity of syphilis. Small-pox has been banished by vaccination, of the usefulness of which the natives are so well aware that they seek it.

ROYAL INSTITUTION OF GREAT BRITAIN.—On *Thursday next (Jan. 30th) Professor B. Hopkinson delivers* the first of two lectures at the Royal Institution on "Recent Research on the Gas Engine," and on Saturday, Feb. 8th, Professor Sir J. J. Thomson begins a course of six lectures on "The Properties and Constitution of the Atom." The Friday evening discourse on Jan. 31st will be delivered by Mr. George M. Trevelyan on "The Poetry and Philosophy of George Meredith," and on Feb. 7th by Sir John Murray on "Life in the Great Oceans."

WEST AFRICAN MEDICAL STAFF DINNER.—The annual dinner of the West African Medical Staff was held at the Walnut Rooms, Grand Hotel, London, on Jan. 15th, *under the genial chairmanship of Mr. J. P. Fagan, formerly* principal medical officer, Northern Nigeria. After the health of the King had been honoured, Sir James Kingston Fowler proposed the toast of "The West African Medical Staff." As a member of the Departmental Committee which inquired into the disadvantages under which the staff laboured, he knew of the admirable work which was being done by members of the staff. Already they had produced a marked diminution in the death-rate and invaliding rate [illegible] *out that the position of the medical officers in relation* to their patients—black and white—and to the various authorities was one of perpetual delicacy. The chairman then proposed the toast of "The Visitors," and coupled with it the name of Sir John Anderson, Permanent Under-Secretary of State for the Colonies, to whom he referred in terms of high appreciation. Sir John Anderson, in reply, spoke of the kindly feeling which he had always had for the West African Service, and gave interesting reminiscences of the old *régime* on the West Coast. He said that, in spite of small numbers and many difficulties, the medical staff had always shown the same loyalty and efficiency throughout the changing conditions. After Dr. W. T. Prout had proposed "Absent Friends" the company reassembled informally in an adjoining room, where the health of "The Chairman" was proposed in an amusing speech by Dr. R. H. Kennan and very warmly received.

working the Act, and that the important minority present at the meeting who were in favour of giving the Act a trial did not succeed in electing their representatives. The grievance of the Handsworth doctors will be removed by coöpting one of their number. It was decided that the Committee should hold office for 12 months.

The Hospital Saturday Fund has not yet suffered to any appreciable extent, and certain firms who at first decided to withdraw are continuing their subscriptions. Most of the important firms are subscribing, and altogether it is not thought that there will be any appreciable falling off in the total amount subscribed.

The various hospitals have decided after Feb. 15th not to treat insured persons except those requiring first aid or treatment which can only be given in a hospital. All patients will be examined, and if not coming in the above categories will be referred to their panel doctors.

Jan. 21st.

SCOTLAND.

(From our own Correspondents.)

The Annual Dinner of the Royal College of Physicians.

The President and Fellows of the Royal College of Physicians of Edinburgh gave their annual dinner in their hall, 9, Queen-street, on Friday, Jan. 17th, when a large number of representative members of the medical profession and guests were present. Dr. J. J. Graham Brown, the President, presided, and the speaking was of a high order at a very successful gathering.

Medical Inspection of School Children in East Lothian.

The school medical inspector, Dr. Buchanan, remarks in his report for last year upon the general improvement noticeable in the condition of children with regard to whom defects had been previously pointed out. Referring to the necessity of keeping the head clean, he mentions that, as it is of course impossible to expect mothers to keep the hair short, much can be done by plaiting it, thus rendering infection much less likely than when the hair is worn loose. Conservative treatment in the way of stopping teeth he considers impracticable for country children, and although the unsatisfactory feeding as a primary cause all through is important, and worthy of every effort for its correction, emphasis should be given to the advisability of brushing the teeth at night as well as in the morning. Referring to the difficulty of obtaining suitable glasses for the children requiring them, he suggests as a remedy the supplying of the medical officer with the requisite testing apparatus, and some arrangement with opticians for the supply of the prescribed glasses at a reasonable rate. He remarks that many children presented by the teachers as suffering from adenoids merely suffer from obstructed nasal passages due to their inability or mere unwillingness to blow their noses properly; every child should, therefore, be provided with a handkerchief of some sort, and should be made to use it properly and reasonably often.

State Insurance amongst Miners.

At a largely attended meeting of Midlothian miners it was, after discussion, unanimously decided to accept the recommendations of the Scottish Miners' Federation regarding the medical attendance on the wives, families, and dependents of members. These recommendations, it will be remembered, are as follows, and have been widely accepted over the country:—

1. That a flat rate be paid by all workers over 16 years of age, half rate between 14 and 16.
2. That, upon the money being deducted at the colliery office, it be lodged at the bank in the name of a committee of workers, who would issue cheques and pay each doctor in accordance with the proportion of persons paying for him.
3. The workers to have absolutely free choice of doctor from the panel.
4. The rate of payment proposed is 1½*d.* per week without medicine, or 2*d.* per week with medicine.

Legacies for Glasgow Infirmaries.

The executors of the late Mr. Edward Davis, of Glasgow, have allotted £40,000 to the Glasgow infirmaries—viz., £15,000 to the Royal Infirmary, £15,000 to the Western Infirmary, and £10,000 to the Victoria Infirmary. The allocation to the other Scottish infirmaries will be made some time in March.

Aberdeen Friendly Societies and the Doctors.

The Aberdeen burgh Local Medical Committee has circularised the local doctors in the following terms:—

> The Local Medical Committee are negotiating with the Friendly Societies regarding the medical treatment of old, and disabled, and other uninsured members of societies, who are earning an income under the income limit, at terms not under those for insured persons. All members of the profession are therefore warned that they must make no private arrangement with such individuals or the societies to which they belong. Recognising the necessity of attending those persons meantime, the Local Medical Committee suggest that any medical practitioner may attend those persons at the rate of 7*s.* per annum without medicine until negotiations are complete.

It is understood that a conference will be held immediately between the Local Medical Committee and the representatives of the Friendly Societies on the question of medical benefit to persons over 65 years of age. The Friendly Societies are willing to give 4*s.* 6*d.* per head, but the doctors desire the same sum as for other insured persons. There is a proposal to group all those persons together and appoint a doctor to give them medical attendance.

Orkney Doctor's Hazardous Journey.

Apropos of the difficulties of medical attendance in the Highlands and islands the following is interesting. On Sunday last a telegram was despatched to Stromness for medical attendance for a crofter on the island of Hoy who lay dangerously ill. There was a heavy gale raging, and no communication between the islands had been possible for days. Nothing short of the lifeboat had a ghost of a chance on the water, so accordingly the local lifeboat, a powerful motor vessel, was manned with a scratch crew and launched, and successfully negotiated the raging sound. A landing had to be effected among the rocks at Hoy, there being no pier. All was done in safety, however, the sick man treated, and a return made.

Extraordinary Case in Aberdeen Infirmary.

An interesting case has recently been treated in Aberdeen Royal Infirmary. A married woman, who was a patient there, was operated upon, when no fewer than 73 ordinary pins, 11 hair-pins, and a small piece of steel were found embedded in the bowel. The woman is unable to account for their presence there, the only possible explanation being that for a considerable period she had during sleep extracted a pin from her nightdress and swallowed it. The patient is recovering.

What Sanatorium Treatment is going to Cost Dundee.

At a meeting of the Insurance Committee, held in Dundee on the 15th inst., the Sanatorium Benefit Committee put forward the [illegible] of expenditure for the year, prepared by [illegible] the medical adviser, in connexion with sanatorium treatment of insured persons:—

Sanatorium treatment during the year of an (estimated) average of 40 insured persons at £1 15*s.* per week ...	£3640
Hospital treatment during the year of an (estimated) average of 60 insured persons at £1 5s. per week ...	3900
Dispensary treatment...	100
Salary of medical adviser, proportion of, say, £500 ...	200
	7840
Deduct grant of 9*d.* for each of, say, 58,000 insured persons	2175
Showing a net estimated deficiency of...	£5665

payable one-half by the Treasury, and one-half by the town council. The proposal was made to reduce the estimate to £1 5*s.* per week for sanatorium treatment, and to 17*s.* 6*d.* per week for hospital treatment. The estimates were, however, finally approved. The number of insured persons in Dundee is 58,630, consisting of 29,160 male and 28,999 female members of Approved Societies, and 352 male and 119 female deposit contributors.

Inauguration of the National Insurance Act in Aberdeen.

Insured persons in Aberdeen are showing great activity in selecting their doctor under the Act. The red ticket is much in evidence, and evidently the impression prevails that it must be presented at the earliest possible moment to the medical man, whether his services are required or not. The work at the infirmary is going on as usual irrespective of whether the patients are or are not insured. A record, however, is being kept of the number of patients who are insured, so that by the end of three months statistics may be available as to what extent insured persons are benefiting from the infirmary

The National Insurance Act in Sutherlandshire

The panel of doctors willing to give service under the National Insurance Act was completed up to time in Sutherlandshire Taking area and population into count the number of insured persons is under the average Up to the present only 3000 slips have been returned by the societies to the Insurance Committee, these being divided between 39 different societies Almost one fifth of the insured population are resident in the Dornoch district As yet not a single application for sanatorium benefit has been received by the County Insurance Committee The deposit contributors do not exceed 50, and even some of those will eventually find their way into societies There are still a few "resisters" in Sutherlandshire, but those must fall into line when liability arises

IRELAND.

(FROM OUR OWN CORRESPONDENTS)

Upkeep of the Collier Dispensary, Dublin

SOME weeks ago the Dublin corporation took over charge of the Collier Tuberculosis Dispensary from the Women's National Health Association with the intention of making it the centre of the tuberculosis campaign in Dublin It now appears, however, that the corporation, though in possession of the dispensary, has no funds to maintain it It is stated that, no provision having been made in the annual estimates, no funds can be advanced from the rates in the current financial year Before provision can be made there are some three months to run At present it is understood that the members of the staff are unable to obtain their salaries, and there is grave danger of the dispensary being, at any rate temporarily, closed The corporation, being involved in this difficulty, suggests that the blame lies with the Insurance Committee, which was not consulted as to the propriety of purchasing the dispensary and has no share in its management At a recent meeting of the Insurance Committee a letter was read from the corporation demanding monthly payments to cover the cost of maintenance, and more recently the threat was held out that the dispensary would be closed if the committee did not find funds Up to the present no patients have been sent to the dispensary by the Insurance Committee, which therefore repudiates all responsibility It is to be hoped that matters may soon be arranged between the committee and the corporation, as it would no doubt be unfortunate if the dispensary were to be closed The affair is typical of the confusion which exists throughout Ireland on the relations between the administration of the sanatorium benefit and the general campaign against tuberculosis

Honour for a Dublin Physician

His Holiness the Pope has nominated Sir Joseph Redmond, an ex-President of the Royal College of Physicians of Ireland, to be a Knight Commander of the Order of the Holy Sepulchre Sir Joseph Redmond is one of the physicians to the Mater Misericordiæ Hospital, Dublin

Scarlet Fever in Londonderry

On Jan 14th it was stated at a meeting of the Public Health Committee that there was an outbreak of scarlet fever in one small and confined area, 23 cases having been notified in the city The cases are said to be mild

The Belfast Medical Students' Association

At a public meeting on Jan 18th, held under the auspices of the Belfast Medical Students' Association in the McMordie Hall of the Queen's University Students' Union, Dr R A Kerr, the president, gave an inaugural address on "Medical Education before the Medical Act, 1858," and Professor A C Geddes (Dublin) followed with a lecture on "Growth and Growing Old " The usual votes of thanks were passed

Sanatoriums and Dispensaries in Co Londonderry

The maintenance of these institutions will be considered at the February meeting of the county council, but it is clear that no permanent scheme will be settled for the treatment of consumptives until it is decided what contribution the Treasury will make, and also what income will accrue from insured persons in the county Only when these questions are answered can it be decided what amount will have to be raised through the rates to cover the certain deficiencies

Jan 21st

PARIS.

(FROM OUR OWN CORRESPONDENT)

The Responsibility of the Medical Man

IN 1905 a female postal employee, 20 years of age, whose cheeks and chin and neck were disfigured with a thick growth of hair, applied to Dr D , a well known Paris physician, to rid her permanently of the embarrassing encumbrance The doctor subjected his patient to the X rays, and the girl was severely burnt, so that in place of hair her neck is now covered with scars Alleging that the doctor had been culpable in his method of application of the rays, she brought suit against him for 20,000 francs in the Tribunal of the Seine Failing in the lower court, she appealed, and the case, which has been going on for eight years and has given rise to two medico-legal inquiries, was heard on Jan 17th before the Fifth Chamber of the Court The Advocate General held that the liability of the medical man was clearly established, for he had failed in his duty, knowing that he was engaged in procedures intrinsically dangerous by absenting himself for however brief periods in place of exercising unbroken watchfulness over the operation, and, further, that it was his duty to warn the girl that the operation was uncertain and dangerous, which he appeared not to have done

The Acoustics of Meeting Halls

On Jan 14th Dr Castex read a paper before the Academy of Medicine on the relation between the acoustic properties of meeting halls and hearing and phonation Undoubtedly, he said, the acoustics of many halls were excellent, but in other cases they were very bad There were yet others in which the acoustic properties were satisfactory for the audience but deplorable for the speaker on account of the strain imposed on him, and *vice versa* though the reason of these differences was not clear Halls might be bad by reason of deadness, of over resonance, or on account of echo The materials used in construction undoubtedly exercised an influence Wood, glasswork, and marble afforded good resonance draperies bad Stone and plaster were regarded as neutral In course of time moreover, the drying of the material improved its sonorousness Cupolas created unfavourable conditions, which exaggerated resonance Speaking generally, good halls were those in which one of the dimensions exceeded the other Round and square halls were less satisfactory Curiously, the slightly deaf heard less well in certain halls than in the open air

A Beneficent Act

Dr Martel, who in 1912 gained the Barbier prize of the Faculty of Medicine for his method of trephining has generously presented the prize, which amounts to 2500 francs, to the Maison du Médecin

The Treatment of Amœbic Dysentery by Sugar Enemata

According to the researches of M Cohendy, enemata of sugar, combined with appropriate regimen and suitable altitude, are of real efficacy in the treatment of dysentery The enema is prepared by mixing in a vaginal douche 250 grammes of the syrup of sugar of the French codex with three litres of boiled water cooled to 60° C When the bowel is especially intolerant six drops of laudanum are added The whole amount is administered if possible, at one injection, and retained from 20 to 25 minutes by lying first on the back and subsequently on the side When there is excessive weakness an enema is at first prescribed both morning and night When the number of stools is reduced by two thirds only one enema daily is given When the stools have become pasty and do not exceed three in the 24 hours, only one enema every two days is given, in the morning An enema every two days may advantageously be continued for ten days following the re establishment of normal movements

Dentists and General Anæsthesia

Two surgeon dentists have been prosecuted for the illegal practice of medicine, having resorted to general anæsthesia for the extraction of teeth. The decree of the court stated that surgeon dentists who qualified subsequently to the Act of Nov. 30th, 1892, having undergone special and appropriate instruction in surgery, had undoubtedly the right to use anæsthetics for their operations without the necessity of employing a medical man, and that no distinction in this respect existed between local and general anæsthetics. On the other hand, this right imposed on them the observance of all proper precautions, the neglect of which would expose them to civil and penal liability. As both the dentists belonged to the above category they were acquitted.

The Skull of Descartes.

Dr. Paul Richer, professor of anatomy at the Ecole des Beaux Arts, who is a talented sculptor and engraver of medallions as well as a member of the Academy of Medicine and the Académie des Beaux Arts, has completed the investigation imposed on him, in conjunction with M. G. Darboux, for the identification of the alleged cranium of Descartes, by comparing it with the different portraits of the philosopher. On a plaster mould furnished him by the museum Dr. Richer pointed out first the clearly marked distinctive characteristics which correlate this cranium with the portrait of Descartes painted by Franz Hals. M. Richer has pursued this method of comparison as strictly as possible, to reduce to a minimum the influence of the personal equation. His method was to make from the portrait by Hals a drawing of the cranium as closely corresponding thereto as possible. A drawing of the skull in the museum was then made in like manner from exactly the same point and to the same scale, and one drawing was then superposed on the other. The first procedure is one of greater strictness than would at first be supposed, and leaves little room for the influence of the imagination. Indeed, a head presents a certain number of precise bony points of indication which Dr. Richer enumerates, and which are particularly apparent in the painting of the Dutch master. These same points are repeated on the mould of the cranium in the museum. By the help of these marks it was easy to place the cranium of the museum with mathematical precision in the position given by Hals to his sitter, and to determine the exact dimensions of the image that it would be necessary to take of it to make the comparison logical and demonstrative. The superposition of the drawings made respectively from the painting and from the cranium in the museum showed an almost exact correspondence. Other drawings, executed under the same conditions from many crania taken at random, on the other hand, showed notable points of difference from the drawing of the portrait by Hals. The same experiment has been repeated with other portraits of Descartes. The comparison of the skulls thus drawn from these different portraits with that of the museum shows sometimes very striking resemblances, but never so complete an agreement as in the case of Hals's portrait. Leaving aside all historical conclusions, the upshot of Dr. Richer's investigations is that the skull preserved in the museum corresponds almost absolutely with that indicated in the portrait of Franz Hals.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Effects of School Education on the Health of Children.

THE Austrian Society for School Hygiene is at present making preparations for an investigation on a large scale into the effects which school education produces on the health of children, special attention being directed to two well-recognised sources of mischief—namely, faulty design of school buildings and faulty educational methods. As regards the buildings, which were originally erected for other purposes and subsequently converted into schools (a frequent course of events in Austria), they as a rule are failures from the hygienic point of view on account of their insufficient admission of fresh air, incorrect lighting, and lack of heating arrangements. The second of the two factors above mentioned is perhaps even more important than the first. It has been proved by statistics that whilst over 90 per cent. of all children entering the school at the age of six years have normal sight, myopia makes itself unpleasantly obvious in the second year, and increases so much in the higher standards that in the "Latin schools" and higher schools over 60 per cent. of the pupils have to wear spectacles. It has also been found that anæmia and scoliosis, not the results of infectious diseases, are frequent concomitants of school attendance. The origin of these abnormal conditions is known, and the prevention of them is one of the objects of the society. In the investigation evidence will be received not only from specialists in the diseases of children but also from general practitioners and experts in various branches of medicine, and attempts will be made to trace the subsequent history of children known to have become ill during school-life.

Congress of Medical Officers of Health.

A short time ago the first meeting, or rather Congress, of the Austrian Medical Officers of Health took place in Cracow, and some of the papers read on this occasion were of general interest to the profession. One of them raised the question of that comparatively rare condition, scleroma, and in the ensuing discussion several speakers recommended that it should be included among the diseases subject to compulsory notification. An international conference was also suggested on this subject, the conclusions at which it may arrive to be submitted to the governments of the countries affected by that disease—namely, Austria-Hungary, Germany, Russia, the Balkan States, Spain, and Sweden. Lately, cases have been reported also from the United States of America. The disease seemed to be increasing, but this is perhaps owing only to the better means of diagnosis now at our disposal. An interesting paper dealt with the medical institutions of certain large industrial undertakings There are in Austria several very prosperous factories and industrial corporations whose premises may be regarded as towns in which many thousands of workpeople are employed. Of late a very commendable system has been introduced, under which, in some of them, medical attendance and sanitary dwellings have been provided for the workers. In the paper referred to an account was given of the hospitals, the schools, the medical supervision, the accident or first-aid appliances, and the arrangements made for the care of the infants to be found in these works. Altogether the standard of hygiene attained in them is much higher than anywhere else in industrial or commercial enterprises in Austria. Another paper gave interesting details as regards the methods used in this country for dealing with town refuse. It was stated that the attempts which have been made to obtain electricity or steam power by the burning of this material have not been suc [illegible] and that better prospects are offered by [illegible] of town refuse as fertilisers for agricultu [illegible] seems to be the method of the future for middle-sized towns.

The Increased Cost of Living in Austria.

The steady advance in the cost of all articles of food as well as of house rent is having an injurious effect on the public health, and the fact that a large proportion of the population is underfed has been officially admitted in connexion with the results of recruiting for the army. Austria is being rapidly transformed into a manufacturing country, the agricultural part of the population now forming less than 40 per cent. of the total. The recruits coming from towns are, as a rule, less well fed than those from the country, unless they belong to well-to-do families. An interesting account of the existing conditions has been furnished in a paper written by Mrs. Granitsch, and read before the Union of Austrian Housewives. She quoted official figures of market prices which prove that the cost of all articles of food has gone up within the last six years by an amount ranging from 18 to 40 per cent. Milk has gone up 30 per cent.; meat, 40 per cent.; sugar, 25 per cent.; flour, 25 per cent; vegetables, 50 per cent.; and fruit, 30 per cent. Among the lower middle class in the population of Vienna the average consumption of meat has gone down to about three ounces per head, because people have "to keep up appearances." The infant mortality has gone up in the same classes to 24 per cent. of all births, whilst the labouring classes, who can spend comparatively more of their income on food, show an infant mortality of 17 per cent. House rent has also gone up during the same period to the extent of 30 or even 100 per cent. Overcrowding, with its natural consequences, tuberculosis and increase of infectious disease, is inevitable.

State exam[illegible]

the local pro[illegible] minority ad[illegible] body composed of all the best teachers in the kingdom, and, with Rome for its headquarters. One advantage of this proposal, according to Professor Durante, would be the natural extinction of the superfluous and less compet[illegible] to co[illegible] centr[illegible] tion [illegible] unive[illegible] stude[illegible] centr[illegible] plan [illegible] and [illegible] must [illegible] Higher Council of Education the Minister maintains them at [illegible] al to their [illegible] ment upon [illegible] members [illegible] the same [illegible] nce these [illegible] have an interest that the age-limit law should be interpreted with [illegible] Another difficulty under the [illegible] in professors, once they have [illegible] pay little attention to their [illegible] obtained the highest position open to them and rest upon their laurels. There should be some stimulus to further work, and this would be provided by the State commission of examiners, to be selected from among the most distinguished teachers. The minority would propose that at 65 every professor should be a candidate for the State commission of examiners. If elected he would remain upon the commission up to 70, at which age he and all university professors would have to retire; but he should retire upon his full salary for the remainder of his life and not upon the pension rate of the other professors. [illegible] of a distinguis[illegible]

things.

The Red Cross Society.

The Croce Rossa Italiana is represented at present in the Balkans by a hospital unit from Bologna and an ambulance from Turin with the Montenegrins, a hospital from Padua with [illegible] and-[illegible] despa[illegible] plete hospital, Professor Burci, director of the Clinica Chirurgica of Florence, is in command, and took with him several of his assistants in the surgical clinic, while the medical direction is in the hands of Professor Baduel, of the Clinica Medica of Florence. This sending to Servia of the principal surgeon of Tuscany with his trained assistants has excited a good deal of comment. On the one hand, it is rumoured that it is a political move on the part of the Government, who has despatched a hospital unit superlatively equipped, both in *personnel* and material, to create a good impression at Belgrade at a moment when Austria has withdrawn her Red Cross units owing to the pressure of mobilisation at home. On the other hand, it is whispered that the Croce Rossa [illegible] retrieve its reputation, somewha[illegible] in Libya, where the lack of di[illegible] the value of the work of some of the Red Cross hospitals and ambulances. By sending a hospital under the command of a senior hospital surgeon, and with the subordinate officers selected from [illegible] the central committee of [illegible] hat it could with confidence face criticism in a foreign country.

Bassini Institute for the Cure of Hernia.

The[illegible] of the[illegible] numb[illegible] Bassin[illegible] The oc[illegible] with, [illegible] words [illegible] the in[illegible] dedica[illegible] with C[illegible] the in[illegible] funds [illegible] Bassini in July, 1909.

NOTES FROM SOUTH AFRICA.

(FROM OUR OWN CORRESPONDENT.)

Unification of the Peninsula Municipalities.

CLUSTERING round the base of Table Mountain are no fewer than nine different municipalities—namely, Cape Town, with a population of 68,742; Sea Point, with 9411; Woodstock, with 28,693; Maitland, with 5762; Mowbray, with 9272; Rondebosch, with 5626; Claremont, with 13,329; Wynberg, with 16,014; and Kalk Bay, with 3526. The municipalities of Cape Town, Sea Point, Wynberg, and Kalk Bay have a sufficient water-supply for their own needs and underground systems of drainage. The other municipalities are without proper water-supplies and are unsewered. The sanitary conditions of the latter are far from satisfactory, and just outside their boundaries slums have grown which are a menace to the health of the whole area. For years the question of unification appears to have been discussed, but the matter so far has never apparently been within the range of practical politics. Last year, however, a conference assembled, and after prolonged discussion evolved a scheme under which it is thought that the municipalities should be able to unite. This scheme is now to be put before the ratepayers of each municipality, when it is hoped that it will be ratified, so that an enabling [illegible] Provincial Council [illegible] e partnership. It [illegible] peninsula can be [illegible] thus establish its [illegible] ry capital of the [illegible] South Africa. To [illegible] atter of astonishment that the area should have remained so long under the control of a number of petty local authorities.

Reorganisation of Asylums.

It is rumoured in Pretoria that the Government has at [illegible] isa[illegible] sed [illegible] sed [illegible] and will become the criminal lunatic asylum The other asylums will be graded each for a different class of patient. Practically all available funds will be spent on the Bloemfontein Asylum, and the accommodation freed by the transfer of criminal lunatics thither will relieve the congestion at other asylums. The scheme sounds attractive, but as the Government is without any recognised medical adviser on questions of asylum policy, and as so far most of its medical administrative work has not been much of a success, it would perhaps be safer to suspend judgment until full details of the scheme have been made public.

NEW ZEALAND.

(FROM OUR OWN CORRESPONDENT.)

Medical Inspection of Schools.

AT last, after much discussion and much urging, New Zealand has undertaken the medical inspection of the children attending the State schools. Four inspectors have been appointed, two male and two female, at a salary of £500 per year. Roughly speaking, there are some 132,000 children attending the schools, and as the schools are spread over an area slightly greater than that of England and Scotland it can easily be seen that some time must elapse before an effective result can be obtained; still, the data acquired will be of great value from both the educational and ethnological point of view. The influence of better climate and easier economic conditions upon child life can by-and-by be investigated. Judging from the very meagre data already acquired it would seem that, age for age, the New Zealand child is taller than the English school child, but that just as many suffer from bad teeth, adenoids, and imperfect vision as at home. The question of how the defective children are to be treated has occasioned much discussion, and it is satisfactory to learn that the present Government has decided not to interfere in any way with the work of the ordinary medical practitioner. The tendency in these democratic colonies is to thrust every burden upon the State, but the profession here has made its voice heard, and the Ministers responsible have openly invited the help and counsel of the medical profession in this work. This is as it should be.

Maternity Homes.

One of the last, and perhaps best, of the acts of the late Mr. Seddon was the establishment of maternity homes, where the wife of the working man could receive skilled attention in suitable hospitals at her confinement. The charges are moderate and the attendants are all properly trained. Considerable discussion, however, has lately taken place as to their administration, and some rather acrimonious criticism and rejoinders have been published. A magisterial inquiry is now being held into the working of the Auckland Home.

The Australasian Medical Conference.

The next meeting of the Australasian Medical Conference is to be held in Auckland early next year, and Dr. A. Challinor Purchas has been elected President.

The Immigration of Consumptives

The question of immigration has occupied the attention of the Government lately. There is need of a greater population in New Zealand, but it has been pointed out that many who have arrived lately have been far from suitable, from a health point of view, to take up the kind of work which is available. Several have landed suffering from consumption in such an advanced stage as to require hospital or sanatorium treatment within a short time of their arrival in the Dominion. It is impossible to impress too strongly on the profession at home the unwisdom of recommending indigent consumptives to "go to the colonies." Every endeavour is made by the authorities to stop such patients landing, and should they pass the cordon their lot is not a happy one. The Government now proposes to appoint a permanent medical officer in London to examine all immigrants before they embark. For two years they had such an officer in London and great good resulted from his work. It would be well for any medical man, before recommending a poor patient to come to New Zealand, to communicate with the High Commissioner, 13, Victoria-street. In this way much trouble would be saved.

Dec. 12th, 1912.

Obituary.

GEORGE ALEXANDER GIBSON, M.D., D.SC. EDIN., LL.D. ST. AND., F.R.C.P. EDIN. & IREL., &C.,

MEMBER OF THE GENERAL MEDICAL COUNCIL; CONSULTING PHYSICIAN TO THE DEACONESS HOSPITAL; PHYSICIAN AND LECTURER ON CLINICAL MEDICINE TO THE ROYAL INFIRMARY, EDINBURGH.

SCOTLAND has lost a brilliant member of the medical profession and one of its leading physicians by the death of Dr. George A. Gibson. The intimation of his death has come as a shock to many, for the serious nature of his illness was not widely known. That a man of 58 years, in the full tide of his usefulness and prosperity, should be prostrated by illness from which he rallies only to be again and again prostrated until the "silver cord" breaks will ever impress men with a sense of helplessness and of ignorance, for beneath it all lie the problems of life. We medical men know what it is to feel thus, and those of us who knew Gibson intimately feel it very specially. The generous, cordial greeting of a nature full of brightness and overflowing with a vitality which seemed to be communicable we know now only as a memory. Life is duller and greyer in Edinburgh by the loss of such a living, active, vigorous, and genial personality from amongst us. No man can take Gibson's place, for there is no one like him, no one who has the characteristics which distinguished him, which made him the centre of many interests in Edinburgh, and one to whom men turned for sympathy and help. It is the *man* we specially mourn, and in doing so we thank God for men of high and honourable ideals, whose characters have never been stained by the mean and contemptible things of life—men who stand for honour, for truth, for straight dealing. And Gibson was one of those men. Having said so much in an endeavour to express the first thought that arises in men's minds as they hear that Gibson is dead, we may pass to a consideration of his professional life, while recognising that it was necessarily determined and coloured by the innate character of the man.

Gibson began the study of medicine in Edinburgh in 1872 Having spent two years at Glasgow University before going to Edinburgh he took the degree of Bachelor of Science at the latter University in 1874, and obtained the Falconer Memorial Fellowship in Geology. His student career was marked by the place he took as a student of science. In medicine the influences which most affected his future were the interest he took in anatomy under the teaching of Professor, now Sir William, Turner, his clerkship with Professor Lister in the Surgical House, and a corresponding experience under Dr. George W. Balfour in the Medical House of the old Royal Infirmary. He graduated in medicine in 1876 and a year later took the degree of Doctor of Science with a thesis on a geological subject. Notwithstanding the attractiveness of science and the ease with which he mastered its details, medicine proved to be still more attractive to him, and he became resident physician in the Royal Infirmary to Dr. G. W. Balfour. At that time Balfour was at the height of his reputation as an authority on heart disease, and Gibson readily turned his interest and his faculties to that line of work. He even then contributed papers to THE LANCET and the *Edinburgh Medical Journal* on the views that Balfour was contending for. His interest in scientific medicine was thus early aroused into activity. Even those early papers showed also the possession of a literary gift, and this gift continued to mark everything that came from his pen as years passed. After his period with Dr. Balfour was completed he demonstrated anatomy for some time under Professor Turner in the University, and when there formed with the late Dr. D. J. Cunningham, the senior demonstrator, one of his strongest and most valued friendships.

In 1878 he became a candidate for the post of assistant physician to the General Hospital in Birmingham, and was successful in his application. While there he was closely associated with two Edinburgh graduates whom he had known as a student—namely, Dr. Saundby and Sir Thomas Chavasse. He did not, however, remain long in Birmingham, for by the end of 1879 he was back in Edinburgh with his name on a door-plate, ready to take

GEORGE ALEX. GIBSON, M.D., D.Sc. EDIN., LL.D. ST. AND., F.R.C.P. EDIN. & IREL., F.R.S.E.,
PHYSICIAN AND LECTURER ON CLINICAL MEDICINE TO THE ROYAL INFIRMARY, EDINBURGH.

whatever of medical practice should offer. He became a Fellow of the Royal College of Physicians of Edinburgh in 1880, and proceeded to the M.D. degree in 1881. He was also elected a Fellow of the Royal Society of Edinburgh. He joined the New Town Dispensary as a member of the staff; he was appointed tutor in clinical medicine in the Royal Infirmary; he lectured on materia medica for a few years, then on practice of medicine in the Extra-mural School of Medicine. Such was the training [illegible] ough who aspired to the "higher [illegible] They had, it is almost needless [illegible] sure to extend their professional knowledge; and to acquire the art of lecturing, and of teaching students. During those years of waiting and of development Gibson wrote a number of papers on cases which came under his observation or on subjects in which he was interested. His first larger effort in Medicine was [illegible] lliam Russell, in the preparation [illegible] Guide to Methods of Clinical [illegible] had succeeded Dr. Gibson as [illegible] ry, and they jointly recognised that the student needed a book of the kind they produced.

[illegible] appointed to the honorary staff of the Royal Infirmary as an assistant physician. In the Infirmary he was attached to Professor Sir T. Grainger Stewart, who most generously gave his assistant physician permission to make full use of the clinical material the wards supplied. He was also given a part in the clinical instruction of the students. This was just the kind of opportunity Gibson required, and he availed himself of it to the uttermost. Two years later he published a brochure on "Cheyne-Stokes Respiration." In 1898 his work on the "Diseases of the Heart and Aorta" appeared; it ran to over 900 pages, and one of its striking features was the wonderful bibliography which accompanied it. This work necessarily gave Gibson the position of an authority on heart disease, for it was evident that he at least knew all that was to be known at the time in this important and extensive department of medicine. In 1901 he edited a two-volume "Text-book of Medicine," t [illegible] c [illegible] l [illegible] 1 [illegible] I [illegible] l [illegible] c [illegible] r [illegible] which appeared in one or other of the weekly or monthly journals, in the *Ed*[illegible] and in *International Clinics.* [illegible] to over 100 in num [illegible] the "Life of Sir William Tennant Gairdner" and the delivery of the Address in Medicine before the British Medical Association at its annual meeting in Liverpool last summer.

When Sir T. Grainger Stewart died Gibson was a candidate for the chair of Practice of Medicine in the University, [illegible] his reputation and popu- [illegible] and extended from [illegible] putation as a "heart [illegible] proportions, his book [illegible] es necessarily marking him out as an able and erudite exponent of the diseases of the organ dealt with in the book and lectures. When he became known his personal attractiveness, his fine, open [illegible] professional brethren who sought his assistance. It is in the full noon-tide of this professional usefulness that he has been cut down. That he enjoyed his success need not be questioned; that he almost gloried in expending physical and mental force even in his consulting work was equally evident, and it cannot be doubted that that generous expenditure of energy for other people, while it attracted them by its very [illegible] dial [illegible] us. [illegible] sful and popular, and in this department, as in all others, there was an expenditure of nervous force that was attractive even if it were not always necessary. This forcefulness drew many men round him if it repelled some; the former class, and it was the larger, found him a kind, sympathetic, and helpful friend. His residents and clinical clerks were devoted to him in more than ordinary degree.

In general medical affairs Gibson took a prominent place in Edinburgh. In his earlier years he was secretary of the Royal College of Physicians, and was for many years a member of the Council of that corporation. He was chairman of [illegible] both fc [illegible] membe [illegible] had quite recently been appointed to represent his College on the General Medical Council. As a physician to the Royal Infirmary he took an active interest in all the varied questions which arose from time to time with regard to the relations of that institution to the medical school, and of the medical school and its teaching to it. His friendly and genial presence will be long missed at those business conferences. He was a great influence in virtue of his open sincerity, straightforwardness, and contempt for what was not straight. He had a withering contempt for meanness and the lower and baser forms of self-seeking and for whoever displayed them. He stood for all that was honourable and of good repute in the profession and in life. He was an optimist by disposition.

To a man like Gibson honours were bound to flow, and he was the recipient of an exceptional number. His reputation as a writer and a consultant entitled him to much, but his power of making friendships and of keeping them and his charming personality contributed some part in bringing them to him. And the list is a long one: he was an M.D. of Dublin, a D.Sc. of Harvard, a D.Sc. of Liverpool, an F.R.C.P. of Ireland, an LL.D. of McGill, and an LL.D. of St. Andrews. In the organisation of the Territorial Forces he held a commission as Lieutenant-Colonel to the 2nd Scottish General Hospital.

Apart from his personal qualities the outstanding professional side of Gibson's character was his intense devotion to the science and practice of his profession and the enthusiasm with which he followed all its advances. He was the exponent of whatever appeared to him to be sound in the latest advances in medical knowledge. He was actively sympathetic towards all forward movement in medicine, and his generous attitude towards other workers explained the personal affection men scattered all over the world felt for him. Few men were so widely known. The exact value of his own contributions to medicine it is too soon to attempt to estimate, meanwhile we state the special influence he [illegible] of students. [illegible] greater is it [illegible] Had it not been for the breakdown in health Gibson would have occupied the Presidential chair of his College this winter, and it is one of the coincidences of life that he should die on the night of the college dinner.

OWEN THOMAS WILLIAMS, M.D. LOND., M.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO THE LIVERPOOL ROYAL INFIRMARY.

WE much regret to record the death of Dr. Owen T. Williams, which occurred on Jan. 15th after a short but acute illness. Dr. Williams, who was only in his thirty-second year, was a brilliant member of the younger group of the medical profession in Liverpool. His career as a student at University College, Liverpool, was one of great distinction, and showed an unbroken record of successes. He obtained, in addition to the diplomas of the Conjoint Board, M.B. Lond. (with honours) (1903), M.D. Lond. (1904), and M.R.C.P. Lond. (1907). He was also a Bachelor of Science of London University. Prior to settling down to work in Liverpool he studied medicine in London, Berlin, Frankfort, and Baltimore. Upon his return to Liverpool he was appointed medical registrar and tutor at the Liverpool Royal Infirmary and honorary assistant physician at the Liverpool Consumption Hospital, which office he resigned in 1910 upon his appointment as assistant physician to the Liverpool Royal Infirmary. He was also lecturer in pharmacology at the University of Liverpool. He was an ardent student at the Johnston

Laboratory of the University, devoting much attention to the bio-chemistry of the processes of disease, especially in relation to problems of digestion and nutrition. He was joint editor with Professor Benjamin Moore of "Researches in Bio-chemistry." Although his career, so full of promise, was cut off at such an early age, he had already achieved a success remarkable in one so young. His contributions to medical literature were very numerous. He was an able teacher, held in high appreciation by the students at the University and at the Royal Infirmary, while his sympathetic character endeared him to all with whom he came in contact. His funeral, which took place on Jan. 18th, was attended by all his colleagues at the Infirmary, and by representatives from all the other hospitals in the city. There was also a large concourse of medical students and nurses from the various hospitals—an evidence of the high esteem in which he was held. He was unmarried.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Jean Morax, founder of the Association Médicale of French Switzerland and an active worker in the cause of hygiene, aged 74.—Dr. Franz Schultz, of Berlin, *privat-docent* of dermatology and radiography as applied to therapeutics.

THE NATIONAL INSURANCE ACT.

THE SPECIAL REPRESENTATIVE MEETING OF THE BRITISH MEDICAL ASSOCIATION.

A FURTHER special meeting of the Representative Body of the British Medical Association was held in the Connaught Rooms, London, on Friday and Saturday, Jan. 17th and 18th. The meeting was called to consider the desirability of releasing members of the medical profession from their pledge and undertakings in connexion with the National Insurance Act, and also to consider the situation created by the attitude of the Government toward the previous decisions of the Representative Body. As before, the proceedings were private, but official communications were sent out each day to the lay press. The following report is from a member of our staff, who was again permitted to be present.

The meeting began at 9.30 A.M. on Jan. 17th, under the chairmanship of Mr. T. JENNER VERRALL. The Representative Body did not go into committee but remained in full session throughout. After the disposal of formal business some time was spent in discussing the order in which the items on the agenda should be taken. It was then decided to express the opinion that where Representatives had received definite instructions from their Divisions, their speeches as well as their votes should be in support of those instructions. The first of the two main issues before the meeting was then raised by a motion proposed by Dr. C. BUTTAR:—

> That while expressing the [illegible] d declining in
> any way to blame, those mer [illegible], compelled by
> economic pressure and the d [illegible] e against their
> wills gone on to the panels, [illegible] expresses the
> opinion that, until agreements to treat insured persons under the Act
> are satisfactory to [illegible] dance with the
> declared policy of [illegible] pledge must be
> considered as still [illegible] to them.

He claimed that their support and consideration were chiefly due to those men who, though faced with ruin, had remained loyal to their pledges. The motion was supported by other London representatives, who felt that the withdrawal of the pledge would counteract much of the success that had been gained in the metropolis through the vigorous campaign of the London Medical Committee. The opposition was led by Mr. J. E. O'SULLIVAN, who declared that the pledge was given in order to produce unity, and that as it had not done so they must quit a fool's paradise; it would not be fair to the loyal men to hold them now to their pledges. Dr. S. HODGSON also argued that since the pledge had failed as a weapon it should be abolished; in his opinion the Salford scheme, which had not involved breaking the pledge, could be made national. The motion was also opposed very emphatically by Mr. C. G. MEADE, and by Mr. J. L. STRETTON in a speech of considerable force. Their main line of argument was that men had been driven upon the panels wholesale, up and down the country; that this fact must be faced; and that the loyal minority must no longer be sacrificed. Other speakers brought forward the inadequacy of the defence funds and the changed attitude of the Association towards coöperation with lay bodies as reasons for granting absolution from the pledge.

Dr. G. E. HASLIP, who had given notice of a motion to proceed to the next business, pointed out the danger that lay upon each side of a straight vote upon Dr. Buttar's motion. He urged the meeting not to express a positive opinion upon the validity of the pledge and undertaking. The solicitor to the Association then gave it as his opinion that by its wording the pledge referred to the policy of the Association, whatever that might be, provided it was constitutionally adopted. This ruling was controverted by Dr. J. H. KEAY, who made it clear, however, that he spoke for himself and not on behalf of his Division. Dr. R. M. BEATON, in support of the original motion, declared that if London's example were followed the profession would win. He asked the meeting to give to a selected body of men plenary powers to meet changing conditions. Mr. E. B. TURNER, who was very cordially received, also strongly supported the motion. He said the fight in London was a test fight, and that if permission could be obtained for the insured of London to make their own arrangements, this would be obtained all over the country. Dr. T. A. HELME expressed deep sympathy both with those whose loyalty had kept them to the pledge in the face of ruin, and those who by treachery and force had been compelled to give unwilling service under the Act. But the latter were the majority, and the pledge as a fighting weapon had failed. The meeting would deliberately inflict ruin on the men with the strongest sense of honour if it held them to their word. The pledge must be absolved, and they must elect plenipotentiaries.

Dr. Buttar's motion was then shelved by a resolution to pass to the next business, and a motion standing in the name of the Canterbury and Faversham Division was taken:—

> That this Representative Meeting, recognising the force of present circumstances and consulting the best interests of the Association and the unity of the profession, now releases all practitioners from their pledge and undertakings.

The mover, Dr. T. B. HEGGS, said that it was designed in order to keep within the fold the good men who had been intimidated into joining the panels. There should, he said, be no discrimination and no recrimination; all practitioners should be released. Thereupon various Representatives gave the history of their local struggles, and showed reason for a general formal release from the pledge. Dr. F. J. SMITH, however, pleaded for a *via media*, which would neither alienate the loyal nor give a triumph to the disloyal. He believed that such a course was offered by an amendment by Dr. Haslip.

After considerable discussion and some modification Dr. HASLIP'S amendment came before the meeting thus:—

> That the Representative Body recognising the economic and other forms of pressure under which many members of the Association consider themselves warranted in taking a certain action with regard to the pledge and undertaking which they signed, and having regard to the strenuous fight which the profession in many areas has carried on, does not consider the present an opportune time to express an opinion upon the action of those members.
>
> That this meeting accordingly proceeds to appoint a committee which may release from the pledge and undertaking the practitioners in any Divisions or Insurance Areas, which give to the Committee satisfactory evidence that this action is desired in such Divisions or Insurance Areas, such release only to be effective so far as regards service by practitioners in their own districts, parishes, and towns, and any acceptance of service by a practitioner in an area where release has not been given will be regarded as conduct detrimental to the honour and interests of the medical profession.

This compromise amendment was seconded by Dr. W. E. THOMAS and supported by Mr. D. F. TODD, who maintained that it backed up those Divisions which were still fighting, while making it possible to absolve from their pledges those Divisions which had had to give in. On being put to the meeting at the close of Friday's proceedings a roll-call vote was demanded and taken. The amendment was lost by 80 votes to 91. The main issue was thus still unsettled at the end of the first day's debate.

At the resumption on Saturday morning the CHAIRMAN addressed the meeting upon the various courses open to it. It was decided that a straight vote should be taken then and there upon Dr. Heggs's motion to release all practitioners from their pledges. A roll-call vote was demanded and taken The result was For the motion 115, against, 35, 5 members did not vote Whereupon the Chairman declared the motion carried by the requisite two thirds majority Immediately afterwards the following resolution standing in the name of the Exeter Division was passed unanimously without discussion —

> Any acceptance of service outside the practitioner s own district parish, or town involving a change of residence for the express purpose *of accepting service will be regarded as conduct detrimental to the* honour and interests of the medical profession

Dr HELME then addressed the meeting Before rescinding the declaration against serving under the Act which was given by the Representative Body at Liverpool, he asked them to register a strong protest against the methods by which panels had been formed He therefore submitted the following motion —

> That this meeting records its emp
> able methods adopted by the Go
> urgency was created under which
> selves threatened with financial rui
> service under the National Insuranc
> considers to be derogatory to the
> interest

This indictment was seconded by Mr TURNER who insisted that throughout its struggle for freedom the attitude of the medical profession had never been political whereas, directly the Government saw that the medical opposition was serious all the resources of the party machine were used to break it up After debate this motion was put to the vote and carried with one dissentient The Liverpool decision was then formally rescinded

Consideration was next given to the future policy of the Association, and the following resolution, giving very full powers to the Council, was passed —

> That the Council be instructed: (*a*) to take all necessary steps to watch and protect the interests of the profession under the National Insurance Act (*b*) to take any opportunity that may be afforded for placing the Representatives of the Association on the Advisory and Insurance Committees (*c*) to obtain statutory recognition of Local Medical Committees in every insurance area (*d*) to collect information as to defects in the Act and Regulations and to take all possible opportunities of remedying them

It was further agreed, amidst applause that in every area where the local profession is strongly organised in opposition to the Act it should be encouraged to remain strong and should be supported to the fullest The questions of central and local organisation, of finance of the position of hospital staffs and of support in the lay press were raised by Dr E R FOTHERGILL and others and after a short discussion these and kindred matters were referred to the Council, including the question of facilities for insured persons to contract out of the Act Another important question which the Council was requested to consider was whether some way could be devised of obtaining more quickly than at present the decision of the Association in cases of urgency, and how far the regulations and by laws of the Association would have to be altered in order to do so It was felt that the present constitution of the Association had become unwieldy in action The Council was also asked to consider the possibility of a postal vote of the whole profession upon questions of policy suggested by the Representative Body

Before the meeting closed on Saturday afternoon Dr J A MACDONALD (chairman of Council) drew attention to the importance of making the records in day books as full as possible since these would be the only evidence of work done under the Act and therefore the only basis for a future demand for better terms The vote of thanks to Mr Verrall for his excellent chairmanship was again carried with acclamation The proceedings terminated with a vote of thanks to the London Medical Committee

---

LECTURES ON ILLUMINATING ENGINEERING —A series of Friday evening lectures on Illuminating Engineering is now in progress at the Polytechnic, Regent street London, W On Jan 17th the first lecture of the second half of the course dealing with illumination and the eye was delivered by Dr W J M Ettles The remaining five lectures, by Mr J S Dow, commencing to day (Jan 24th) will deal with practical applications including such questions as the measurement of light and illumination, colour, shades and reflectors and indoor and outdoor illumination These lectures should prove of interest to medical men at least as much as to the public

> is not
> rising

All I can say is that, as a result of the working of the National Insurance Act, the practices of many doctors will probably be doubled in value.

Sir J. D. Rees: Does the right honourable gentleman think that the medical profession are no judges of their own business?—Mr. Masterman: The members of the medical profession are coming in to work the Act in large numbers.

The Insurance Act in Argyllshire.

Major Hope asked the Secretary to the Tre[illegible] tion had been called to the meeting of the Arg[illegible] mittee on Jan. 10th, when it was resolved that [illegible] county were such that the panel system, worked at its best, would not give a complete and satisfactory medical service, and that it should be represented to the Insurance Commissioners that a large Treasury grant was necessary for Argyllshire in order that insured persons might receive proper medical treatment; and whether the probable necessity of such grants being made was included in the £1,650,000 estimated by the Chancellor of the Exchequer on Oct. 23rd, 1912, as the additional cost of medical benefit under the National Insurance Act.—Mr. Masterman said in reply: Argyllshire is one of the districts within the terms of reference of the Highlands and Islands Committee, whose report is now under consideration.

Major Hope: After the report has been dealt with and acted upon, will the insured person be provided with medical benefit or the contribution returned?—Mr. Masterman: I think there is medical benefit for all the insured persons in Argyllshire.

Sir G. Younger: Will the right honourable gentleman say how it is possible in these scattered areas, with matters as they are now, to do [illegible] men?—Mr. Masterman: All the medical [illegible] vice under the National Insurance [illegible] a special mileage grant in those scattered areas.

The Marquis of Tullibardine: With regard to the question of mileage, has that been promised to the country doctors?—Mr. Masterman: Yes, all the doctors have been promised that in sparsely populated areas there will be a special grant.

Assistants under the Insurance Act.

Mr. Worthington Evans asked the Secretary to the Treasury whether, where a panel had been constituted, it was necessary for panel doctors' assistants to be also on the panel before they were permitted to treat insured persons; and whether the locum tenens of a panel doctor must be on the panel before he could look after the panel doctors' patients.—Mr. Masterman answered: Where a panel is constituted it is open to a qualified assistant or locum tenens, if his principal assents, to place his name on the panel. An assistant or locum tenens whose name is not thus on the panel may only treat insured persons on behalf of his principal when the latter is precluded by urgency or other professional duties, absence from home, or other reasonable cause from giving personal attendance to an insured person under his care.

Mr. Worthington Evans: Would the ordinary two or three weeks' holiday be considered a reasonable cause?—Mr. Masterman: Yes, it would include a case of that sort.

In reply to Mr. John Ward, Mr. Masterman stated that it was the duty of the Insurance Committee to take any necessary steps to secure that the service provided by any assistants was satisfactory, but, subject to this, the salary of such assistants was a matter for their principals and themselves to determine.

Nursing Arrangements under the Insurance Act.

Sir Archibald Williamson asked the Secretary to the Treasury whether any arrangements had yet been made to provide nursing for insured persons; whether such arrangements, if any, had been made with existing district nursing associations; whether these associations were willing to undertake the work; and how much it was proposed to pay per insured person for the nursing required.—Mr. Masterman [illegible] urses is a matter for the Insurance [illegible] yet [illegible] loy- [illegible] sion of the kind has been made in some cases in connexion with sanatorium benefit.

Sanatorium Treatment in Ireland.

Mr. Hugh Barrie asked the Secretary to the Treasury whether he would now state the amount of the intended grant in aid to be given to Irish county councils to assist in providing sanatoria treatment for uninsured persons, and to meet the cost of providing sanatoria treatment for insured persons, in so far as insurance contributions would be insufficient for the purpose.—Mr. Masterman furnished the following written answer: The intention is that the amount of the annual grant should be one half of the total net cost incurred, within reasonable limits, by or on behalf of a county or county borough council, or combinations of these bodies, according to a scheme approved by the Irish Local Government Board, in treatment of tuberculosis in the area, of all persons, whether insured persons, dependents of insured persons, or persons who are neither insured persons nor the dependents of insured persons, after deducting the amounts received from Insurance Committees out of the moneys available under the National Insurance Act for sanatorium benefits and any sums received in respect of the treatment of non-insured persons or otherwise. A circular explaining the conditions of the grant in detail is now in draft and will shortly be issued by the Irish Local Government Board.

Inclusive Fees at English Universities.

In reply to Mr. Whyte, Mr. J. A. Pease (President of the Board of Education) said: The Universities in England and Wales in receipt of Exchequer grants charge inclusive fees in the great majority of cases, universally so in the Faculty of Medicine.

Monday, Jan. 20th.

Friendly Societies and Canvassing.

Dr. Esmonde asked the Secretary to the Treasury whether he was aware that some benefit societies had issued circulars to their members urging them to select particular doctors on the panel, and had also sent canvassers to their members to inform them that they were required by the society to select certain doctors who were named; whether in the majority of cases this was being done with reference to members of those societies who only became members of any Friendly Society for the first time under the provisions of the National Insurance Act, and who were not patients of the particular doctors named; and whether, in view of the effect of pressure such as this or canvassing carried on [illegible] oured by the officials of [illegible] one on the local panels, [illegible], the Insurance Com[illegible] prohibit societies from [illegible] swered: Every insured [illegible] the panel by whom he wishes to be attended, and the issue of any circular which conceals this fact would be unjustifiable. If my honourable friend will inform me of any actual case in which a circular has been issued stating that members are required by the society to select certain doctors who are named, I will see whether any action should be taken.

London County Medical Committee.

Mr. Touche asked the Secretary to the Treasury whether his attention had been called to a resolution passed by the London Medical Committee protesting against the recent formation of what was termed the London County Medical Committee (from among the members of which an executive committee had been f[illegible] in no sense consistent with reason, or in p[illegible] National Insurance Act, could the Insuranc[illegible] that such a committee could be regarded [illegible] duly qualified medical practitioners resident in the county of London; and could he say what steps were proposed to be taken by the Commissioners to secure that any body which was recognised under the Act satisfied the provisions of the Act.—Mr. Masterman replied: The committee referred to in the question has not yet been recognised by the Commissioners under Section 62 of the Act. The Commissioners, when considering applications made to them by a medical committee for recognition under that section, require full information as to its composition and the procedure by which it was brought into existence.

The London Panel.

Mr. Touche asked the Secretary to the Treasury how many of the doctors on the panel for the county of London were also on the panels of neighbouring counties.—Mr. Masterman said in reply: I believe that some doctors resident near the border of the administrative county of London have arranged to continue to treat insured persons on the other side of that border under the Insurance Act as formerly in private practice. A complete answer to this question would involve the separate examination and comparison of the panels of Middlesex, Surrey, Kent, Essex, West Ham, and Croydon. I will send the honourable Member, if he desires, the printed lists of doctors for all these areas.

Major White also asked whether any doctors were entered on more than one panel in the county of London, and, if so, how many; and how many of these had been registered in more than two districts.—Mr. Masterman answered: There is only one panel for the county of London. Its division into lists for the separate boroughs is for the assistance of the insured persons in their selection of a doctor within convenient distance of their homes. Medical men were asked in what districts they wished to serve, and the lists were prepared accordingly. The number of doctors on the London panel in the first list was 760, and I learn that more than a hundred new names have since been received.

Contiguous Panels.

Major White asked the Secretary to the Treasury whether any medical men were entered on more than one panel under the National Insurance Act; if so, how many; and how many of these had been registered in more than two districts.—Mr. Masterman replied: Yes. Where a medical man living near the boundary between two contiguous areas has patients in both he has, of course, placed his name on the panel of both. It would obviously have been detrimental to the interests, not only of the medical men but of insured persons, that any such artificial divisions as arise from local government boundaries should preclude insured persons from continuing to receive the services of their own doctors. The figure of 15,000 given as the number of doctors on panels in Great Britain was arrived at after making a liberal discount for cases of this kind.

The Panel Lists.

Mr. Hogge asked the Secretary to the Treasury to state what steps had been taken to acquaint insured persons with the names and addresses of doctors on the panel; and whether lists of their names and addresses had been circulated to each insured person, or, failing that, whether their names and addresses had been advertised in the local press.—Mr. Masterman said in reply: Lists of medical men on the panel have been set up in all post offices, and in offices of the Customs and Excise Officers, at Police Stations, Labour Exchanges, and hospitals, and have also been sent to the local branches of Approved Societies who asked for them. Lists have not been supplied to individual insured persons, but certain newspapers have, I believe, published local lists.

Mr. Newman asked whether, before admitting the name of any practitioner who might apply to have his name placed on a panel in their area, the Insurance Committees had been directed by the Insurance Commissioners to investigate the validity and worth of any foreign or [illegible] ch applicant might adduce as proof of ability to [illegible] of him.—Mr. Masterman answered: I am not [illegible] practitioners have been included on any panel except duly qualified medical practitioners—that is, practitioners for the time being registered under the Medical Acts. No foreign or colonial practitioner is entitled to be registered unless he possesses the qualifications prescribed by the Medical Act, 1886.

Mr. Newman asked the right honourable gentleman whether his attention had been drawn to the difficulty caused to insured persons who were obliged to select a medical practitioner from their local panel owing to his status and degree being stated by means of letters of the alphabet only: whether on the Kensington panel two practitioners were described as L.K.Q.C.P.I. and L.R.F.P.S.G. respectively; and whether, in a revised or any subsequent copy of the panel that might be issued, the Insurance Commissioners would give directions that any qualifications in possession of the practitioner should be set out in more popular language.—Mr. Masterman said in reply: The question of the manner in which lists of doctors on the different panels are published is entirely a matter for the Insurance Committees [illegible] junction with the medical men on the panel. I [illegible] local variations in the proce[illegible] have cause[illegible]

[illegible]lection of Panels.

Mr. [illegible]ARMAN asked the Chancellor of the Exche[illegible] [illegible]ntative Men of the decision arrived at on Saturday last [illegible] to allow Meeting of the British Medical Association, whether it further time for the completion of the doctor[illegible] it was intended to set up the Local Medical[illegible]—Mr. LLOYD GEORGE said in reply: So far as I am aw[illegible]ls are still open in the greater part of the kingdom, and [illegible]en may still send in their names. The date of publicat[illegible] names rests with the Local Insurance Committees. Ap[illegible] for recognition by the Local Medical Committee may b[illegible] any time to the Insurance Commissioners for approval.

Mr. TOUCHE also asked how many of the doctors whose names appeared on the London panel had resigned.—Mr. MASTERMAN (in a written answer) replied: Four doctors on the London panel have withdrawn, one of them because he is leaving London.

Medical Services and Snowstorms.

The Marquis of TULLIBARDINE asked the Secretary to the Treasury if an insured person wired for a doctor and was unable to get medical assistance owing to the roads being blocked with snow, the amount of premium due for medical benefit for that period would be refunded.—Mr. MASTERMAN replied: The answer is in the negative.

UGANDA HEALTH REPORT.

REPORT on the Blue book of the Uganda Protectorate for the year 1911-12, prepared by Mr. H. R. Wallis, C.M G, Acting Governor, has just been presented to Parliament by the Colonial Office In the section devoted to vital statistics and public health it is stated that the present estimated population of the Protectorate is 2,843,325 In 1911 the European births numbered 18, marriages 4, and deaths 11 There are no reliable returns as to the number of births, marriages, and deaths of natives The health of European officials has been good 395 cases were placed under treatment in hospital, as compared with 356 in the previous year, the increase being doubtless due to the larger number of officials resident. Malaria and diseases of the digestive system were responsible for the greatest number of admissions There were 4 deaths of officials caused by illness during the year, and 4 cases of invaliding There were 2 cases of blackwater fever, both of which recovered. The total number of officials resident during the year was 233. In regard to the European population generally, the number of admissions to hospital was 662, as compared with 630 in the previous year. In 1911 the principal causes of admission and the numbers treated for diseases mentioned were malaria, 203, blackwater fever, 4, spirillum, 5; dengue, 5, enteric fever, 5, diseases of the respiratory system, 18, and digestive diseases, 152 Complete medical statistics of the European community are not, however, obtainable, as a large proportion of the non official population do not come under the treatment of Government medical officers The health of Asiatic officials in Government employ is only moderate There were 748 admissions to the sick list during the year and 5 deaths Of these numbers, 334 admissions were due to malaria and 5 to blackwater fever, which terminated fatally in 2 cases The total number of natives treated in all Government hospitals and dispensaries was 70,571, with 251 deaths, as compared with 66,365, with 263 deaths in the previous year. The rate of infant mortality among natives is alarmingly high, and is influenced probably by the prevalence of venereal disease and by the persistence of unhygienic customs amongst natives at the time of childbirth.

During the year under review measures for the control and suppression of sleeping sickness were greatly extended Additional areas were marked out and declared "infected areas" on the shores of Lake Albert, in the Nile district, and in the region of Lakes George and Edward Porter traffic to the Lado enclave has been limited to journeys on certain selected routes which are believed to be particularly free from danger of infection Porters are permitted to proceed only as far as the Congo posts near the border, and a limited time is allowed for the journey All porters proceeding along these routes are medically examined and registered Extensive clearing was commenced on the banks of the Victoria Nile between Foweira and Masindi Port to render the waterway safe A considerable movement of population from the infected area of Unyoro is in course of arrangement. In the Nile districts, owing to the scattered distribution of Glossina palpalis and to the present uncertainty in regard to the local efficiency, as carriers of sleeping sickness, of G morsitans and G pallidipes, which abound in this region, no extensive movements of population are at present considered advisable The total number of deaths from sleeping sickness reported was 1437, as compared with 1546 in the previous year.

Thirty four cases of plague came under treatment, of which 29 were fatal, the returns for the previous year were 17 cases and 13 deaths According to native returns the distribution of deaths from plague was as follows Buganda, 613, Busoga, 1256; Bukedi, 1773, Unyoro, 31; Toro, 22, total, 3695 These returns cannot be regarded as entirely trustworthy, but the medical officers are of opinion that the disease is on the increase in Bukedi. As has been previously reported, plague is widely endemic in the Protectorate, and minor epidemics, which are seldom heard of, occur from time to time among the natives of various parts A temporary plague hospital, with an isolation ward for contacts, exists at Mbale, which is the centre of the endemic area. Chiefs are encouraged to build segregation huts in villages, and are instructed to report all cases immediately on occurrence Native inspectors are employed to see that these instructions are carried out, and also to supervise the isolation of infected persons and contacts and the burning of infected clothing and huts No case of plague has yet occurred among the Asiatics in the infected area

In regard to small pox, medical officers visited epidemic areas, vaccinating contacts and many others, and destroying infected clothing and huts The epidemics which occurred were effectively checked Vaccination was performed in 3003 cases, as compared with 2491 in 1910 and 1654 in 1909 A permanent isolation hospital exists in Entebbe At other stations temporary huts are erected as required and destroyed when the outbreak is over Arrangements have been made with the native chiefs in Buganda and Bunyoro for the local segregation of lepers in small settlements Difficulties are experienced in providing for regular food supply and in ensuring adequate supervision, The sanitary condition of the principal stations is reported to be improving steadily. Organised systems for the removal and disposal of sewage and rubbish exist in larger townships and are being gradually extended It cannot be said, however, that the organisation of any of the stations is as yet completely satisfactory Lack of funds prevents more rapid progress In regard to the affairs of Uganda generally the year is reported to have been one of marked progress and development

ESPERANTO AND THE INTERNATIONAL MEDICAL CONGRESS

To the Editor of THE LANCET.

SIR,—At a meeting of the Universal Medical Esperanto Association (Tutmonda Esperantista Kuracista Asocio) held in Cracow last August a committee was appointed to organise an Esperanto section in connexion with the forthcoming International Medical Congress, similar to that which was held during the last International Congress in Budapest A considerable number of Russians, Poles, Hungarians, &c, stated that they would go to London if hopes could be held out of having such a section Will any Esperanto medical men or others willing to help kindly communicate with me?

I am, Sir, yours faithfully,
G JAMESON JOHNSTON, F R C S Irel.

13, Lower Fitzwilliam street, Dublin

THE NEED FOR AMBULANCES IN THE COUNTY OF LONDON

AT an inquest held at the City Coroner's Court recently attention was drawn *once more to the need for an efficient ambulance service* within the jurisdiction of the London County Council, such as already is provided in the City In the case in question the deceased was taken ill with apoplexy at the Islington Empire Theatre, and had to be conveyed *on a hand ambulance to St Bartholomew's Hospital,* where he died, more than half an hour thus elapsing before he could receive medical attention Dr F J Waldo, in commenting upon this to the jury, expressed his desire that the London County Council should go into the matter *and provide ambulances, but at the same time* he intimated that in his opinion the Council's numerous and varied functions already sufficiently occupied the attention of its members, and that the provision of ambulances would better be entrusted to *the Metropolitan Asylums Board Unquestionably the enormous* development of London's telephone system and of motor-car traffic has had little or no result in a phase of metropolitan life in which the telephone and the motor vehicle might by now have been playing *extremely useful parts Hardly any circumstance indirectly connected* with medical or surgical science could do more to increase the efficiency of our hospital system than the institution of a service which would *bring the patient suddenly taken ill or injured to the hospital with* the least possible loss of time, *and with the least possible likelihood of* injury through recourse to an unsuitable mode of conveyance,

NOTE BOOKS FOR DOCTORS AND NURSES

WE have received from Messrs Scott and Bowne copies of their useful little waistcoat note-books and diaries for 1913, adapted respectively for doctors and nurses The diary is a week to an opening with extra memoranda and cash pages *The doctor's book also contains data* relating to ambulances, bacteriological research laboratories inebriate retreats, homes, sanatoria, and lunatic asylums, legal information relating to medical matters, weights and measures, doses, X ray *work, the usual tables relating to incubation* periods, obstetrics, poisons, quarantine, weight and height, pulse and temperature, and so forth, addresses of associations for providing embalmers, male nurses and masseurs, messengers, and, of course, postal, wages, and other every-day information [illegible] this information is also contained in the *Nurse's Diary*, also data relating to the sick-room and cooking for the sick, confinem[illegible] disinfection, first aid, laying out, medical abbreviations and term[illegible] and much other matter likely to be of special service to nurses, not forgetting a space for register of engagements. Both books are neatly leather bound—the doctor's in blue, the nurse's in green—and contain a pencil in the back. As we are asked for suggesti[illegible] [illegible] might say that it would be a great convenience if [illegible] pockets for cards and postage stamps, so as to obviate the necessity of carrying a separate card case.

◆

Mr. John Dunlop, L.R.C.P.—The specimens sent are probably acari, but they are difficult to identify because they have been crushed between the slides. The best treatment would be by a weak solution of formalin—say 1 in 10. The acari probably do not come from the leather, but from the stuffing of the furniture. The solution suggested will not affect most kinds of stained leather.

Dr. R. A. Burns (Alabama).—Our correspondent's questions are too vague for detailed and precise answers. 1. He does not state in what part of the world it is wished to take the special courses in surgery, obstetrics, gynæcology, and diseases of children. 2. It is not clear which of the many contributions to the literature of hookworm disease and pellagra would be suitable.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

A DIARY OF CONGRESSES

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement The following Congresses Conferences, and Exhibitions are announced —

March 17th 20th (Paris) —International Congress of Physical Education

(Easter week) (Berlin) —Fourth International Congress for Physiotherapy

April 3rd-9th (London) —International Congress of Historical Studies

" 6th-12th —Health Week

" 22nd 25th (London Horticultural Hall) —Nursing Conference and Exhibition

" 26th (Ghent) (opens) —International Exhibition

July 7th-12th (Exeter) —Twenty-eighth Congress of the Royal Sanitary Institute

---

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor"

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

THE INDEX TO THE LANCET

THE Index and Title page to Vol II of 1912 were given in THE LANCET of Dec 28th, 1912.

VOLUMES AND CASES

VOLUMES for the second half of the year 1912 are now ready. Bound in cloth, gilt lettered, price 16*s*, carriage extra

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s*, by post 2*s* 3*d*

To be obtained on application to the Manager, accompanied by remittance

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W C, are dealt with by *them?* *Subscriptions paid to London or to local newsagents* (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c, should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows —

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 1 0	One Year	£1 5 0
Six Months .	0 12 6	Six Months .	0 14 0
Three Months . .	0 6 6	Three Months .	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs 50 per month)

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied

SOLE AGENTS FOR AMERICA—Messrs WILLIAM WOOD AND CO, 51, Fifth Avenue, New York, U S A

LECTURE III.[1]

Delivered on Jan. 14th.

MR. PRESIDENT AND GENTLEMEN,—It is my intention to-day to direct your attention to the progress which has been made towards the identification in the human body of the particular *contagium virum* which we have now ascertained to be the immediate cause of endemic goitre. We have seen that all attempts have so far failed to identify it outside the body of man; we will now proceed to consider what evidence there is of its existence in the body of sufferers from the disease.

On the entry of the *contagium virum* with the food into the human intestine three courses are open to it: (1) it may invade the blood and tissues, giving rise to a chronic infection; (2) it may reach the thyroid gland and exert its harmful influence in the gland itself; (3) it may remain in the intestinal tract, there producing poisonous substances which, on absorption, initiate the changes in the thyroid gland.

We shall now consider the evidence for and against these three possible modes of action of the organism, examining, in the first place, the possibility of a chronic blood infection.

THE BLOOD IN GOITRE.

In the year 1898 Dr. Grasset published an account of a hæmatozoon, which he found in the fresh peripheral blood of sufferers from goitre of 10 to 15 days' standing. Though I have often sought, in recent cases of the disease, for the parasitic elements described by Grasset, I have consistently failed to find them. McKenzie records a like experience. None of the numerous observers who have studied the blood in goitre have recorded the presence of blood parasites. Grasset himself does not appear to have followed up his discovery with more detailed observations as to the life-history of the organism. The Swiss Goitre Commission has devoted much attention to the question of the presence of blood parasites in goitre, but always with negative results.

Nor have blood inoculation experiments yielded any positive results. In 1907 I inoculated 2 c.c. of blood taken from a young man, the subject of a recent goitre, into the flank of a young monkey. Two inoculations were made at intervals of seven days, but no results were observed. The monkey remained in perfect health.

PARASITIC THYROIDITIS OF CHAGAS.

It is in these particulars, as well as in its symptomatology that the endemic goitre which we are discussing differs from the "parasitic thyroiditis" recently described by Dr. Carlos Chagas. This disease, which is endemic in Brazil, approximates in one of its forms so very closely to endemic [illegible] a slight [illegible] fore you [illegible] to point [illegible] me, the [illegible] implies, is essentially an acute condition. It is attended with pain in the thyroid gland, continued fever often high, enlargement of the lymph glands, spleen, and liver, and nervous symptoms of peculiar malignancy. Trypanosomes are readily found in the blood stream during the acute stage of the disease. The temperature remains elevated while the parasites are present in the blood. It affects young infants chiefly, and gives rise to an enormous mortality amongst them. If the disease does not terminate fatally within 15 to 30 days of its onset it lapses into a chronic form of illness, which is said to be characterised by the presence of goitre, often of very large size, and symptoms due to partial or complete loss of function of the thyroid mechanism, nervous symptoms, and affections of the heart. These symptoms are classified by Chagas, who groups them into "four forms." Patients show a peculiar colouring of the skin "different from the paleness of anæmia, and likened by Professor Austrigesilo to the appearance of pale bronze." Dependent on the degree of thyroid derangement the symptoms may be slight, of moderate intensity or very pronounced. It is possible, therefore, to meet with cases which are *practically indistinguishable from the usual type of* goitrous individual met with in endemic localities in Europe.

According to Chagas, these large degenerated goitres are the result of a schizotrypanum infection acquired during the early years of life. It is not possible to distinguish such cases from cases of true "endemic goitre" by blood examination, since the trypanosome, which is said to cause the goitre, disappears from the blood stream after the acute symptoms have subsided.

I find in the writings of Chagas and his helpers no reason to doubt the accuracy of many of his conclusions with regard to the acute form of the disease he has described. It is not equally clear, however, that the chronic goitres are due to the same cause which gives rise to the acute illness. Professor Kolle, of Bern, has informed me that, though he has produced some thyroid swelling in a rabbit by the injection of a culture of schizotrypanum cruzi into the artery leading to the gland, it has not been possible to induce the formation of a true goitre in this way.

Thyroid enlargements amounting to the formation of true goitre can, according to Bayon, be brought about by the injection of certain bacteria or their toxins into the gland; so that did the injection of a culture of trypanosomes give rise to a like result it could not be regarded as peculiar.

The work of Chagas is of the greatest interest, since, if it is confirmed, we shall have to recognise the existence of a form of endemic thyroiditis, due to a protozoal organism, together with the very important fact that a form of endemic goitre *can be conveyed from man to man by certain biting* insects.

We must not lose sight of the possibility that two forms of [illegible] I may use the term—may prevail [illegible] istrict, in the same way that two different forms of splenomegaly may be found to be endemic in the same locality. Nor must we lose sight of the possibility that a trypanosome infection may coexist in the same individual with goitre initiated by the endemic influences I have indicated to you. The only criticism of Dr. Chagas's admirable work which *I am at present disposed to make is* that he does not appear to have excluded, in a manner which leaves no room for doubt, the possibility that the form of trypanosomiasis which he has described may be an infection superimposed upon "endemic goitre," and not, as he considers the infection to be, the veritable cause of this malady in Brazil. However this may be, there can be no doubt of the differences which exist between the "parasitic thyroiditis" endemic in Brazil and the goitre endemic in Europe and in the Himalayas. Nevertheless, Dr. Chagas's work reminds us forcibly that all cases of goitre in endemic localities need not necessarily originate from the same cause.

Returning to our consideration of

THE HÆMATOLOGY OF ENDEMIC GOITRE,

we find that blood changes of a fairly definite character are almost always to be met with. I have made blood counts in 73 cases of goitre at all stages of the disease. I found that the polymorphonuclear leucocytes are below normal in 98·9 per cent. of cases; the small mononuclear leucocytes are above normal limits in 92·5 per cent. of cases; the eosinophile cells are above normal limits in 88 per cent. of cases, while the large mononuclear cells are increased in only 23 per cent. of cases. It was observed that these changes are most marked in recent cases.

Examination of *the fæces for intestinal worms* showed

---

[1] Lectures I. and II. were published in THE LANCET of Jan. 18th (p. 147) and 25th (p. 219), 1913.

1639

that while often to be found, there was no evidence of their presence in the majority of the cases. The eosinophilia, therefore, cannot be accounted for in this way.

In blood taken from the thyroid gland itself by means of a hypodermic needle it was found that eosinophile cells were present in very large numbers. Twelve cases were examined in this way.

In the year 1906 I drew attention to these blood changes. Marine published similar findings in 1910, and pointed out that there was in addition a diminution of the hæmoglobin index and of the number of red blood corpuscles. The total number of leucocytes he found to be reduced in simple goitre. Miss Charlotte Millar has also found in cases of simple goitre an absolute reduction in the numbers of polymorphonuclear leucocytes down to 50 per cent. of the normal, and a hyperlymphomatosis of from 30 to 50 per cent. More recently Bauer, working in Tyrol, has also observed the increase of lymphocytes in this disease, while Lidsky and Kottman have found that the coagulability of the blood is increased.

The blood changes of exophthalmic goitre so far resemble those of endemic goitre that the polymorphonuclear cells are diminished and the mononuclear cells are increased in numbers. But by a somewhat strange antithesis, observed by Marine, the reduction of the red blood corpuscles and the increase of the eosinophile cells present in endemic goitre contrast with an increase in the former and a decrease in the latter in the exophthalmic form of goitre. These blood changes are not sufficiently characteristic as to make it possible by blood examination to distinguish, in doubtful cases, between endemic and exophthalmic goitre. In opposition to Professor Kocher, who emphasises the importance of blood examination as a differential test in early cases of Graves's disease, I am strongly of opinion that it is valueless for this purpose, and that its employment is calculated to lead to many errors of diagnosis and to the adoption of surgical methods of treatment which are not justified by the gravity of the patient's condition.

The blood changes in cases of endemic goitre give one an indication that perhaps in the intestinal tract is to be found the seat of infection, since similar changes are met with in certain intestinal infections.

Having failed, then, to find in the blood any indication of a chronic infection, we now turn to an examination of the thyroid gland itself and the changes which it undergoes in this disease.

PATHOGENESIS OF ENDEMIC GOITRE.

By reason of the lack of material it is not possible to study in the human subject the very earliest changes which result in the development of goitre. Goitres which are removed by operation are usually the seat of extensive degenerative changes which obscure the picture of the fundamental process. Our knowledge, therefore, has been acquired by a study of uncomplicated thyroid enlargements in animals, and is largely the result of the work of such observers as Horsley, Marine, Lenhart, Bayon, and others.

Now, though the following account of the pathogenesis of goitre, which I have compiled from the writings of our best-known workers on the subject, and largely verified by my own histological studies, is, I believe, *in the main, an accurate record of the changes* which take place, yet I am myself not fully satisfied that it affords a full and satisfactory explanation of the different stages in the development of parenchymatous and colloid goitre.

According to Marine and Lenhart, the earliest changes are to be observed in the blood-vessels, the epithelium, and the stroma of the organ, and these changes vary with the degree and stage of the process. There is, in the first place, a markedly increased blood-supply to the gland. The capillaries and larger vessels of the stroma are dilated and there is an increased secretion of colloid substance which is more liquid, thinner, and takes the stains much more lightly than usual (Bayon). The next step in the process is an increase in size of the cells lining the vesicles, which may vary greatly in degree. The cells may be cubical in mild degrees to high columnar in the severer degrees of hyperplasia. They are more closely packed, more highly granular, and the nucleus is more deeply staining than is the case in the normal gland. Should these changes occur rapidly the cellular lining of the vesicle may undergo folding or plication, an appearance which is constantly observed in the severer degrees of hyperplasia, but never to the same extent in simple goitre as in exophthalmic goitre. The cells may become so high as to fill the whole lumen of the vesicle, as I myself have observed to be the case in goats in which severe degrees of hyperplasia were induced by experiment. At this stage of the process the gland may not have increased in size; and there may be little or no colloid in the vesicles, its increased fluidity possibly favouring its discharge into the lymphatics and blood stream. According to Marine, however, there is a degree of enlargement proportional to the degree of hyperplasia. Marine and Lenhart have called this "the pre-clinical stage of goitre."

Coincident with the process of parenchyma hyperplasia, hyperplastic changes take place in the connective tissue stroma. These fibrotic changes may be slight or marked, diffuse or localised.

Bayon has demonstrated that, following the glandular hyperplasia, a desquamation of the epithelial lining of the vesicles occurs. The desquamated cells coagulate and form with the colloid "casts," which, in his opinion, further irritate the epithelium to increased secretion and proliferation. The increased secretion is retained in the vesicles, and as a result of the pressure of the colloid the lining epithelium of the vesicles loses its polyhedral shape and becomes cubical or even pavement-like. The dilated vesicles lose their rounded outline and become irregular in shape. Their walls become thin and may rupture, the coalescence of adjacent dilated vesicles giving rise to cyst formations. Vestiges of previous active hyperplasia are to be found in the form of occasional projections of the wall of the dilated vesicles, which are covered with cubical or columnar epithelium according to the stage of the process, in an increase in the connective tissue stroma and in obliterating endarteritis. Marine and Lenhart describe the process as a reversion of the gland to the "colloid state," and speak of the goitres so formed as "colloid goitres," a term which is, I think, more applicable at this stage of the process than "parenchymatous goitre," and one which should not be limited to those "parenchymatous goitres in which the colloid material is unusually abundant and obvious" (Berry).

The whole process is catarrhal, and in a sense compensatory in character, and results in the formation of an increased amount of colloid substance, which is to a large extent retained in the gland. The changes appear to differ in no essential from those described by Hürthle, Horsley, Murray, and Edmunds, as taking place in the portion of thyroid left behind after partial thyroidectomy in animals—a fact to which McKenzie drew attention in 1898.

"Colloid" goitres formed in this way may be subject to recurring attacks of hyperplasia, and consequently the gland increases in size by a step-like process, which accounts for the increases observed in the size of goitres at certain seasons in goitrous localities.

Since King and Horsley demonstrated that by pressure the colloid secretion could be made to pass from the alveolus by way of the interalveolar lymphatic spaces to the lymph vessels, it has been generally accepted that this is the route which the secretion follows in its course to the blood stream. Biondi has shown that it may also find its way into the lymphatics as a result of rupture of the alveolar walls; while Hürthle has demonstrated, by the injection of Berlin blue into the lymphatic spaces, the existence of minute intercellular channels which form lines of communication between the alveolus and the interalveolar lymph spaces. If it is true that under normal circumstances the thyroid secretion is discharged into the blood stream in this way, then in the development of goitre it appears evident that some impediment must exist to the escape of the secretion by way of the lymphatics. The work of Gutknecht, Todbelsky, and Horne indicates that this is probably the case, since colloid is absent from the lymphatics in a large proportion of cases of goitre, but present in the veins of the enlarged gland. Forsyth has made the interesting suggestion that in goitre there is a retention of colloid in the gland owing to the obstruction of the main lymphatic channels by a parasitic organism, and that the secretion, finding its way blocked by the usual channel, reaches the blood stream *via* the veins—a circumstance which would account for the absence of myxœdema in most cases of goitre.

The changes which I have described as characteristic of endemic goitre occur, as a rule, uniformly over the whole gland, but may be more apparent in some parts than in others. Amongst vesicles which have undergone the process of active hyperplasia and subsequent distension with colloid may be found others which have not been affected and which retain their normal characters.

There may also develop in the gland rounded or circumscribed masses apart from the main body of the goitre. These are usually called "simple adenoma" or "fœtal adenoma," according to their histological appearances. They may occur either in the form of a single nodule or of several nodules scattered through the gland, which, in developing, encroach on the normal tissues, causing atrophy. This adenomatous form of goitre is one which is very common in goitrous localities. It is, according to Bircher and Wilms, almost constantly met with in the artificially induced goitre of rats, in which animals a preponderating tendency to nodose hypertrophy is said to occur.

It is important to remember that degenerative processes early attack the thyroid gland which is, in the first instance, the subject of continued and increased glandular activity. The point is of the greatest importance to the physician, for it is obvious that to be successful, medicinal treatment must be commenced early, and that once degenerative processes have progressed to any extent, and have resulted in the formation of adenoma and cysts, medicinal treatment in any form must prove unavailing. In the great majority of all cases of parenchymatous goitre which come before the physician, the functional activity of the gland is impaired to some extent, and the patient exhibits symptoms corresponding in degree to the degree of impairment of glandular function.

We may sum up the changes which take place in the thyroid gland as a result of goitrous influences by saying that these influences *at first stimulate the organ to increased activity, but that the increased activity so induced is early followed by damage to the secretory epithelium, and by degenerative changes which impair its functional activity.*

THYROID HYPERPLASIA VARIOUSLY INDUCED.

Bayon has shown that all stages of simple goitre can be produced in various ways by experiment: (1) by ligaturing the thyroid artery; (2) by the injection of an emulsion of soot in sterile water into the thyroid gland; (3) by the injection of typhoid toxins into the gland; (4) by poisoning with phosphorus. As a result of his experimental work he has concluded that "any cause which is capable of altering the function of the thyroid so as to damage its secretory epithelium can lead up to the production of colloid, diffuse, or nodular goitre." When I come to consider the experiments dealing with the transmission of goitre from man to animals, it will be shown that thyroid enlargement can be produced by feeding goats on a highly fæcal polluted water, and that very marked hyperplasias can be brought about as a result of feeding these animals with cultures of micro-organisms grown from the fæces of goitrous individuals. The many forms of "thyroiditis" are examples of goitre due to micro-organisms of the class "bacteria," while certain protozoal organisms can also cause thyroiditis. Lastly, goitre can be produced by the poisonous substances generated in the body of man and animals, either as a result of metabolic processes or by the normal bacterial inhabitants of their intestinal tract. Examples of goitre due to poisons of this nature are the goitre of pregnancy and the congenital goitre of puppies born of a partially thyroidectomised bitch.

We thus see that "goitre" can be produced in a number of ways, but chiefly by the action of micro-organisms and toxic irritants. It is highly probable, therefore, that in the case of "endemic goitre" there must exist an irritant either in the form of a micro-organism present in the gland itself or of toxic substances circulating through it.

THE STERILITY OF GOITRE.

Many attempts have been made to find in the thyroid gland more definite evidence of the nature of the goitre-producing substance than that which is afforded by the pathological findings I have described. Since the year 1902 I have made repeated, but unsuccessful, examinations of blood obtained by thyroid puncture in recent cases of goitre.

Very careful histological examinations have been made by Hofer, Bonnet, and Pick in the case of trout goitres, but with negative results so far as the detection of a micro-organism was concerned.

Dr. Helen Chambers has examined 259 cases of innocent goitre, 30 of which were pure parenchymatous enlargements. She has recorded that—

> Several hundred sections have been made in some of the cases, and these have been treated by various methods of staining organisms in tissues. Bacteriological examination, including animal inoculation, has been made in a few cases. The result has been entirely negative. Nevertheless, the histological characters suggest a toxic substance *present in the thyroid gland—in some cases diffuse, in others localised.*

Professor Kolle, of the Swiss National Commission on Goitre, speaking on the work of this Commission, has stated:—

> Neither the use of the newest staining methods—for instance, Giemsa's staining of smear preparations, as well as the silver method, [illegible]

The Swiss Commission also carried out extensive inoculation experiments with a view to determining whether micro-organisms or other substances existed in the thyroid which could produce the disease when introduced into animals. Pieces of goitre were transplanted into the abdominal cavity of four apes. After one month the transplanted tissue was absorbed. The animals remained healthy. An emulsion of fresh goitre juice was injected intravenously into three rabbits, one dog, and one monkey. The result was *nil*, the animals remaining perfectly healthy. A similar emulsion was injected intravenously into five rabbits every week for three months. The result was negative.

Weichardt and Schittenhelm have recently demonstrated the presence of antibodies in the blood serum of rabbits inoculated with goitre-producing water. Their experiments, which promise useful results, are not yet completed.

Gelbride has examined bacteriologically the contents of eight cystic goitres. In seven the results were negative; in the eighth he obtained a culture of the streptococcus vermiformis of Sternberg. Horand also has reported the presence of a parasite in a goitrous cyst. In neither of these cases, however, is there sufficient evidence to justify the suspicion that the organisms found are causal agents in the production of goitre. The greatest care must be exercised in investigations of this kind. I, myself, have amongst my records a microphotograph of a diatom (navicula) found in the blood obtained by thyroid puncture from a case of goitre. Having regard to the fact that Klebs found naviculæ to be present in goitrigenous and absent in non-goitrigenous waters, the discovery of this organism exercised my mind greatly for some time. My repeated failure to meet with it again in the blood convinced me that the source of the diatom was the water in which my hypodermic needle had been sterilised. Nor is this the only organism I have met with, but in the other cases also I have convinced myself that their presence was accidental.

We see, then, that up to the present time there is no evidence of the existence in the thyroid gland of goitrous individuals of any specific *contagium vivum*—whether microscopic or ultra-microscopic—to which the malady could be attributed. We are led to consider, therefore, whether the increased glandular activity, and the changes which follow it, may not be due rather to some toxic substance circulating in the blood stream and emanating from an organism resident in the intestinal tract.

It is impossible to prosecute the inquiry without some appreciation of the proper functions of the thyroid gland.

THE FUNCTION OF THE THYROID GLAND.

The fact that the antitoxic and bactericidal resources of the body are largely dependent on the functional perfection of the thyroparathyroid mechanism is, I believe, as clearly established as is the influence of this mechanism on metabolism. I desire now to draw your attention to a few proofs of the thyroid gland's antitoxic action.

Sajous showed in 1902 that the injection of various bacterial toxins into man and the lower animals excited, more or less actively, according to their virulence, the thyroid gland's functional activity, while Bayon's researches show that the injection of bacterial toxins into the gland may lead to the actual formation of goitre. Farrant also has lately induced marked thyroid hyperplasia by the injection of diphtheria toxin into guinea-pigs; he demonstrated that the hyperplasia so induced could be controlled and greatly mitigated by the administration of thyroid extract at the same time as the toxin. Fassin found that the germicidal power of the blood was diminished by thyroidectomy. Charrin, Vincent, and Jolly drew attention to the fact that animals deprived of their thyroid glands are rendered very susceptible to infectious diseases, to which they readily succumb. Hürthle observed that by ligaturing the bile-ducts in dogs the thyroid secretion was increased; he attributed this change to the passage of certain constituents of the bile into the blood. Although this is doubtless possible, it may with equal reason be assumed that the operation, by depriving the intestinal contents of the biliary secretion, hastens putrefactive processes, and thereby fosters the absorption of an excess of toxic substances into the blood stream from the intestine. Turrô has found that the juices of swine's and sheep's thyroids dissolved almost entirely the comma, typhoid, and anthrax bacilli, as well as the bacillus coli communis and streptococcus. Gley showed that the blood serum of thyroidectomised dogs is more toxic than normal serum and gives rise to convulsions when injected into animals, while de Luca and d'Angerio have found that the urine of these animals contains a higher percentage of toxic substances than is normal, and that thyroid extract administered to them counteracted this toxicity.

While making every allowance for errors of observation, these and other findings of a like nature justify the belief that the thyroid gland contributes largely to the body's antitoxic and bactericidal resources.

In some animals low in the phylogenetic scale—amphioxus, ascidians, and lower vertebrata—the thyroid gland communicates with the pharynx by means of a duct. In fishes also this is the case, so that in these animals the thyroid secretion enters the body by way of the alimentary tract. It may be, as has been suggested by Andriezen, that the thyroid secretion is absorbed in fishes through the vascular arches, and enables the respiratory organs to take up oxygen and carry on the gaseous metabolism more readily. But, in view of the secretion's antitoxic and bactericidal action, its discharge into the pharyngeal cavity is, to my mind, an indication that it is intended to exercise this action in the alimentary tract. We have seen that trout develop goitre when confined in filthy, unhygienic tanks which are swarming with micro-organisms. It is highly probable that under these circumstances the thyroid gland is stimulated to increased activity, and that in consequence there is, at first, an increased discharge of colloid into the alimentary tract. But the reaction of the gland is early followed by an imprisonment of colloid in the organ, and other degenerative changes occur, which result in the formation of visible goitres.

These facts suggested to my mind the possibility that the *contagium vivum* of goitre might exist in the intestinal tract, a possibility to which the results of blood counts also pointed. Blum, in 1900, expressed the belief that goitre was due to the presence of a *living excitant in this situation*, but he advanced little proof in support of his contention. Let us now examine the evidence which, I believe, demonstrates the truth of this view.

INTESTINAL ANTISEPTICS IN THE TREATMENT OF GOITRE.

Acting on the assumption that the intestinal tract might be the seat of infection, I began in the year 1905 to try the effect of intestinal antiseptics in selected cases of the disease. My first case was that of a man suffering from a fairly large parenchymatous goitre. The man was admitted into hospital and salol prescribed. No result was observed during the first ten days. I then left Gilgit, and on my return, six weeks later, I found a very notable change had taken place in this case during my absence. Not only had the goitre almost completely disappeared, but there was a striking change in the man's general appearance. He was considerably thinner and the skin had lost its muddy look and become much clearer. Thinking that residence in hospital, and the comparative freedom from goitrous influences which is thereby entailed, had been in part responsible for the change, I commenced treating selected cases as external patients. All these patients continued to live under the same conditions of life as those under which the disease had been acquired; I further selected thymol as likely to prove a more efficient intestinal antiseptic than salol (*vide* Figs. 9 and 10).

I have treated well over 100 cases of goitre in this way, but in 82 only was I able to observe the final result of the treatment. Of these 82, 68 were cured, or so markedly benefited as to be practically so; while 14 were unaltered, or only benefited to a very slight degree. All were selected cases. Thirty-three were of three months' standing or less, 25 were of 12 months' standing or less, while 24 were of a year's standing or more. The great majority of these cases which could be regarded as cured or very greatly benefited were of less than one year's standing. A few were of longer duration. These were uniform [illegible] : some of them showing marked [illegible] the vessels of the neck. The majority of such cases react at once to treatment by thymol, and in some the swelling disappears with great rapidity. One meets with a few cases, however, which, though they appear to differ in no essential from others, are quite uninfluenced by the treatment, or indeed by any other medicinal treatment employed. Older cases respond less readily to treatment, but in some of these also the results are quite surprising. Cases in which there are changes in the gland of a permanent character are either not influenced by the treatment, or a certain shrinking of the gland around the cyst or tumour mass takes place, rendering them more clearly defined. This treatment, like all others of a medicinal nature, is applicable only to cases of recent origin where degenerative, cystic, and adenomatous changes have not yet taken place. Where such changes have occurred no form of medicinal treatment is of the slightest use.

When thymol is prescribed in such large doses as 10 gr. twice daily the patient's dietary should, of course, contain no solvents of the drug; otherwise most unpleasant symptoms of thymol poisoning may result. When this rule is observed no ill effects follow its use, even when administered for such long periods as three months. Apart from a few complaints of burning pain around the anus, none of my patients have been in the least inconvenienced by the treatment. The drug is best administered in the form of a coarse powder washed down by a draught of water. The bowels should be active, and if there is any tendency to constipation an occasional purge should be given.

A striking result of this treatment, and one which is noticeable in most of the photographs I have shown, is the loss of subcutaneous fat which occurs. The patient becomes more clean-limbed and the skin assumes a healthier tint. β naphthol, also, acts beneficially, though I have not given it the same extended trial as thymol.

The chief interest which attaches to the treatment of goitre by thymol is etiological rather than therapeutical. The germicidal power of thymol is very great. Ratimoff placed it fourth in the list of germicides, arranged according to potency (mercuric chloride, silver nitrate, iodine, and thymol). It is interesting to note that it is only slightly

DESCRIPTION OF ILLUSTRATIONS IN SUPPLEMENT.

FIG. 6.—Shows appearance of neck at the time the experiment was commenced. Measurement, 33 cm. The experiments which are illustrated in Figs. 6, 7, and 8 are described in THE LANCET of Jan. 25th, p. 224.

FIG. 7.—The same subject. Photograph taken on the thirtieth day of the experiment. Measurement, 35 cm.

FIG. 8.—The first line represents the appearance of the normal thyroid gland of a white rat. The second shows the result of feeding rats on non-goitre-producing water. The third the result of feeding rats on goitre-producing water. The fourth the result of feeding rats on a goitre-producing water passed through Jura earth and through a Berkefeld filter. The fifth shows goitres produced in rats by the residue left on the membrane of the dialyser and by the residue left on the candle of a Berkefeld filter after the passage of goitre-producing water. (By permission of Dr. E. Bircher.)

FIG. 9.—Case 62. Appearance of patient's neck prior to the commencement of treatment by thymol. Measurement, 41½ cm.

FIG. 10.—The same case eighteen days after the commencement of treatment. Measurement, 38 cm.

FIG. 11.—Goitre in a boy, aged 12, treated by "soured milk."

FIG. 12.—The same case after thirty days' "soured milk" treatment. Note complete disappearance of goitre and great loss of subcutaneous fat.

FIG. 13.—Shows the changes brought about in the size of the thyroid gland of rats as a result of giving th [illegible] period of nine months. The first line [illegible] of normal rats as seen from behind; th [illegible] produced goitres; whilst the third l [illegible] which resulted from the consumption of water raised to a temperature of 99° to 100° C. for several minutes. (See issue of Jan. 18th, p. 154.)

FIG. 14.—Parenchymatous goitre treated with "coli" vaccine. Before, 42 cm.

FIG. 15.—Parenchymatous goitre treated with "coli" vaccine. After, 37·5 cm.

less powerful than that "specific" for goitre—iodine—in its germicidal action.

Cooper, in his recent researches on the bactericidal action of the cresols and allied bodies, states that in the absence of particulate organic matter thymol is 25 times as powerful a disinfectant as phenol, and 10 times as powerful as the cresols to bacillus typhosus. He also showed that emulsified thymol is 23 times as powerful as phenol in the absence of particulate organic matter, and 7½ times as powerful in the presence of 3 per cent. of dried fæces. So that it is a very powerful germicide indeed.

Now thymol is not readily soluble in water (1 in 1500), so that in the absence of any of its solvents, such as fats, oils, lcohol, and vinegar, it is very sparingly absorbed into the system when administered in the form of a coarse powder. Its action is, therefore, in all probability a local one in the gut. I regard the action of the drug as very strong, though not conclusive evidence that the habitat in man of the organism responsible for the production of goitre is the intestinal tract. The drug appears to act either by destroying the living *excitant* of goitre, or by reducing its numbers or activity in such a way that the production of toxic substances is lessened, and the thyroid gland is relieved of the excessive demand for its secretion which necessitated the hypertrophy.

It is well known that iodine is regarded as a specific for goitre. I believe that its beneficial action is largely due to its *powerful germicidal properties, which are even more* marked than those of thy[illegible] ing to the thyroid that [illegible] activity of its secretion [illegible] stration of iodine also leads to leucocytosis, a very desirable object to attain where there is usually a marked reduction of the polynuclear cells of the blood. Its use is attended *with a loss of weight and subcutaneous fat, and if the treatment* is carried to excess dangerous wasting and palpitation of the heart and other symptoms may arise.

LACTIC ACID BACILLUS IN THE TREATMENT OF GOITRE.

The action exercised by the lactic acid ferments when applied to the treatment of recent cases of goitre affords additional evidence that the agent responsible for the production of goitre has its habitat in the intestinal tract of man. In carrying out this line of treatment I have used the fresh cultures in milk of the bacillus bulgaricus. I have treated up to the present time only eight cases in this way, but the results have been very striking. My patients were under treatment for a period of one month to six weeks. To some 12 to 20 oz. of "soured milk" were given every morning before the first meal of the day, to others 10 oz. were given in the morning and 10 oz. in the evening. The cases were all of several months' standing, and during treatment there was no change whatever in the manner of life of the patients. They were treated as external cases, and carried out their work in the fields as usual. The results cannot be attributed, therefore, to change of locality, habits of life, or water-supply. Of these eight cases, four were cured, two improved, and two showed no appreciable difference after six weeks. In those cases which were benefited by the treatment it was observed that the thyroid gland began to show evidence of diminution in size about the tenth day of treatment, and that the patients lost flesh. (Figs. 11 and 12.) The latter fact is of great interest, inasmuch as it is observed to occur also *as a result of the treatment of goitre by means of iodine* and thymol.

VACCINES IN THE TREATMENT OF GOITRE.

The next step in my investigations was the employment, in the treatment of the disease, of vaccines prepared from bacteria found in the fæces of sufferers from goitre. A full account of the preparation and use of these vaccines will be found in a paper published in THE LANCET of Feb. 10th, 1912, p. 357. Three vaccines were so employed. The first, a composite vaccine made from such organisms as grew on Musgrave's agar; the second, a "coli" vaccine made from the patient's own strain of bacillus coli; the third, a vaccine prepared from a spore-bearing organism which was isolated from the fæces of a goitrous pony. The results obtained by the use of these vaccines were very remarkable, and a complete disappearance of the thyroid swelling took place in all [illegible] in the [illegible]atment with "coli" vaccine in a man aged 23.

Vaccines prepared from organisms derived from sources other than the patient's own fæces were then employed, and equally striking results were obtained with a staphylococcus vaccine—the staphylococcus having been derived from a case of caries of bone. Considerable interest attaches to the fact that a staphylococcus vaccine exercises such a remarkable influence on the enlarged thyroid gland, since the organism is also a normal inhabitant of the intestinal tract of man. The significance of these results is discussed in the paper above referred to.

The vaccine treatment of goitre is further confirmation of the view which I have enunciated that goitre is due to the presence of a living organism of disease in the intestinal tract. It demonstrates also that the thyroid gland is markedly influenced by the nature of the bacterial flora of the gut, and that one of its chief functions is to protect the body from the many toxic substances which find their way into the blood stream from the alimentary canal. The remarks which I have made with regard to the treatment of goitre by thymol apply also to its treatment by means of vaccines. The method is of use only in fairly recent cases of the disease in which degenerative processes have not yet involved the gland to any extent.

FIG. 16.

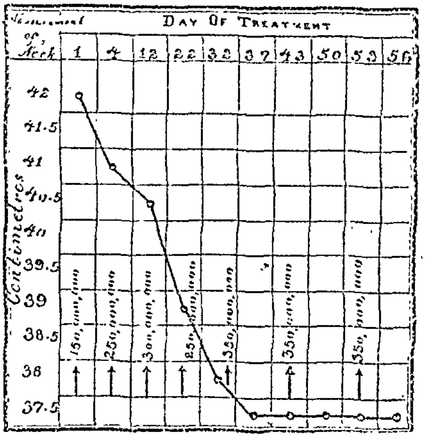

Chart showing measurements of neck at various stages of treatment with *doses and times of administration of* vaccine.

A conspicuous feature of this treatment, and one which brings it into line with the treatment by iodine, intestinal antiseptics, and the bacillus bulgaricus, is the fact that the patients lose flesh and the skin becomes of a healthier tint. The common factor in all these methods of cure is to my mind the fact that they destroy or inhibit the action of the toxic agent of the disease. Iodine, thymol, and B. bulgaricus do so by their antisepticising action in the gut, while the vaccines employed attain the same end by a more complicated process of immunisation. Cases in which these various therapeutical measures may be employed with success are those which also respond to treatment by thyroid extract, showing that the goitre is a response to a demand for thyroid secretion which, when supplied artificially, enables the hypertrophied organ to subside. Iodine, thymol, and vaccines destroy or inhibit the action of the agent which institutes the demand, but since they do so comparatively rapidly, and while the organ is still enlarged, the secretion which is stored up in the dilated vesicles is for a time in excess, the demand for it having been removed. The excess of secretion, therefore, which continues to reach the blood stream, until such time as the gland regains its normal equilibrium, exerts its influence in increasing the metabolic processes of the body, and a loss of subcutaneous fat is the result.

Let me now briefly recapitulate the evidence in favour of the intestinal tract as the seat of infection in goitre. The toxic agent of the disease reaches this situation through the medium of water or food, a situation into which the secretion of the thyroid gland is known to be thrown in certain of the lower animals. This secretion possesses, to a high degree, bactericidal and antitoxic powers. A powerful antiseptic which exerts its action in the gut cures the disease, as does the lactic acid bacillus, which acts by inhibiting the production by the intestinal flora of poisonous indols and phenols. Lastly, vaccines, prepared from organisms which are known to be normal inhabitants of the bowel, cause the disappearance of goitre. It is my belief that short of the actual identification of the toxic agent of the disease, stronger evidence of the truth of my contentions could hardly be conceived.

It has been objected that intestinal toxæmia is nowadays made to account for many disorders for which no better explanation can be found. This may be so, but I hope that those who have listened to my argument will agree with me that the evidence before us removes this view of the causation of goitre from the region of doubtful hypothesis to that of practical certainty. It is true that nature has provided a sentinel in the liver, standing at the exit of the portal system, to deal with the poisons which are produced in the intestinal tract, but nature has provided also an additional safeguard in the shape of an antitoxic secretion in the blood, which encounters the poisons absorbed from the bowel at the very point of their absorption. To emphasise the importance of the thyroid's antitoxic function is not to minimise the importance of the liver; both are units in the great army of defence, and to put one such unit out of action is to throw a greater strain on another.

LECTURE IV.

Delivered on Jan. 16th.

Mr. President and Gentlemen,—The process of reasoning which we have followed has led us to the conclusion that the *contagium vivum* of endemic goitre inhabits the intestinal tract of man; but the culminating test of the truth of this conclusion can only be afforded by a recognition of this organism as present in the intestinal content and its transmission from man to animals. This point has not yet been attained.

The Fæces in Goitre.

I have examined microscopically the fæces of a large number both of goitrous and of normal individuals in Gilgit.

In a paper published in 1909[2] I have figured and given a brief description of the varieties of amœbæ met with. In 103 cases of goitre in which the fæces were examined I found amœbæ present in 87. In 48 cases they were found in large numbers, in 27 in moderate numbers, and in 12 only after considerable time had been spent in searching for them. The fæces of 101 non-goitrous individuals, living in the same locality, were also examined. In 29 of these amœbæ were present; the infection was plentiful in 8, moderate in 9, and scanty in 12. The eight-nucleated cysts, which are typical of one of the varieties of amœbæ met with, were found also in samples of fæces sent to me by Colonel Macnab, I.M.S., from cases of the disease which occurred in the boys' school at Simla. *While no definite statement can be made as to the pathogenicity of these amœbæ*, their *possible* importance is obvious when it is remembered that goitre is due to an organism carried by water.

I must take this opportunity to point out clearly that I do not assert, and have never asserted, as is sometimes stated by continental writers, that goitre is due to the presence in the intestines of the amœbæ I have described. My study of these organisms was but the beginning of an investigation of the protozoa parasitic in the intestines of residents in localities where goitre is endemic—an investigation which I regard as of primal importance.

Various experimental procedures have been adopted by the Swiss Goitre Commission with a view to demonstrating the presence of a specific virus in the fæces: 1. Intravenous injections of a filtered solution of *normal fæces* have been made into rabbits. The operation was repeated seven times in one case, but with negative results. 2. Intravenous injections of a filtered solution of *goitrous fæces* have been made into rabbits. The operation was repeated eight times. The thyroid did not enlarge. 3. Intravenous injections of a solution of normal fæces in chloroform and of goitrous fæces in chloroform have also given negative results.

There still remains, therefore, much work to be done; and it is my hope, should the circumstances of my service permit, to continue the prosecution of research in this direction.

Experiments dealing with the Transmission of Goitre from Man to Animals.

Since the year 1906 I have repeatedly endeavoured to transmit goitre from man to animals by infecting the water-supply of the latter with the fæces of sufferers. No effects being observable in dogs, I undertook a series of experiments on goats in the hopes of arriving at results of a positive character.

Female goats were selected for these experiments. They were taken from the same flock, were between the ages of one and two years, and were not pregnant. This point is of importance, since the increased activity of the thyroid gland during pregnancy would vitiate the results observed on microscopical examination of the organ. The goats were brought from a non-goitrous locality, high up in the mountains, about 40 miles distant from Gilgit. Their thyroids were carefully examined and were found to show no signs of hypertrophy. In the majority either the gland could not be distinguished from the surrounding tissues or could be felt only with the greatest difficulty. Where the organ was palpable it was found to be oval in shape and about the size of a small almond. The goats were divided into batches, which will be referred to as I., controls (3 goats); II., Batch X (6 goats); III., Batch Y (7 goats). Each batch was confined in a separate pen. The animals were all fed on leaves and young branches of trees, in order to exclude as far as possible sources of contamination from the soil. The experiment was designed so as to foul the drinking water of Batches X and Y, while that of the controls remained pure.

The apparatus which I devised for this purpose is represented by the figure (Fig. 17). It consisted of a drum, A, which was fitted with a tap. A covered wooden box, B, having a perforated false bottom of wire gauze under which was a wooden trough sloping towards an outlet pipe, B. This outlet pipe led into a flask C, which was fitted with a perforated cork, so as to ensure freedom from contamination by soil, dust, &c. The drum, A, was filled with a non-goitre-producing water which had been previously boiled. A trickle of water from the drum, A, was allowed to pass continuously into the box, B. This box was partially filled with soil taken from the most goitrous village in Gilgit. The soil was sterilised by steam at 230° F. for 30 minutes, and was then mixed with the fæces of sufferers from incipient goitre. Fresh fæces were added to the mixture several times a week during the course of the experiment. The water from the drum, A, trickled into the box, B, saturated the mixture of sterilised earth and fæces, and, passing through the perforated bottom of the box, found its way, by means of the wooden trough and outlet pipe, B, into the corked flask, C. This was the only drinking-water provided for the goats of Batches X and Y.

A separate apparatus was used for each batch. In the case of Batch Y, however, 500 earthworms were introduced into the box, B. The earthworms were added with a view to determining whether they might act as intermediate hosts for the organism suspected of causing the disease. The water-supply of both batches was, therefore, grossly contaminated with the fæces of sufferers from goitre, while in the case of Batch Y the drinking-water contained such additional matter as was derived from the excreta of the earthworms.

The experiment was commenced on Oct. 13th, 1910, and terminated on Dec. 15th, 1910. The thyroid glands of the controls showed no change during the 64 days of the experiment. In the case of the goats of Batches X and Y, however, it was observed that (1) all the animals lost in weight; (2) many of them suffered from diarrhœa; (3) 50 per cent. of the goats in each batch showed enlargement of the thyroid gland.

It was observed that the thyroid glands of two of the goats in Batch X showed signs of enlargements, as determined by palpation, as early as the thirteenth day of the experiment. A second noticeable feature was the manner in which the glands fluctuated in size. It will be remembered that goitre in man, whether artificially produced or naturally acquired, shows the same tendency to fluctuate in size in its early stages This is due, I believe, to the alternate emptying and distension of the vesicles with colloid

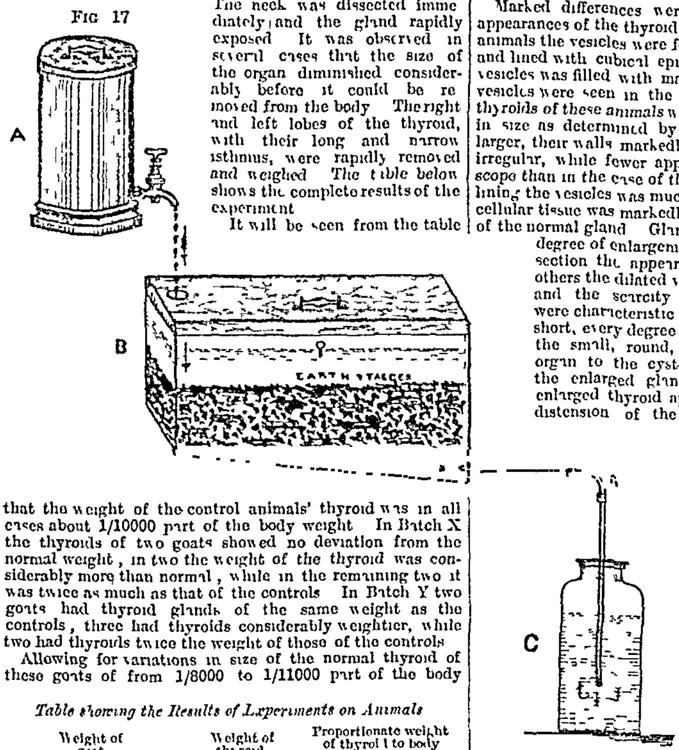
---

[2] Quarterly Journal of Microscopical Science, 1909.

The animals were killed by a goorkha skilled in severing the head from the body at one stroke of his kookrie (knife) The neck was dissected immediately and the gland rapidly exposed It was observed in several cases that the size of the organ diminished considerably before it could be removed from the body The right and left lobes of the thyroid, with their long and narrow isthmus, were rapidly removed and weighed The table below shows the complete results of the experiment

It will be seen from the table that the weight of the control animals' thyroid was in all cases about 1/10000 part of the body weight In Batch X the thyroids of two goats showed no deviation from the normal weight, in two the weight of the thyroid was considerably more than normal, while in the remaining two it was twice as much as that of the controls In Batch Y two goats had thyroid glands of the same weight as the controls, three had thyroids considerably weightier, while two had thyroids twice the weight of those of the controls

FIG 17



Apparatus employed for contaminating the water

Allowing for variations in size of the normal thyroid of these goats of from 1/8000 to 1/11000 part of the body weight, it will be admitted that about 50 per cent of the animals in Batches X and Y showed enlargements of the thyroid gland It is possible that conclusions based on the weight of such a variable organ as the thyroid gland may prove fallacious, but as the goats were taken from the same flock and were of the same season and sex the margin of error was reduced to the minimum Since the same results were observed in the goats of Batches X and Y, earthworms would not appear to be concerned in the spread of the disease

Table showing the Results of Experiments on Animals

Weight of goat	Weight of thyroid	Proportionate weight of thyroid to body weight
I —Controls—three in number—which Consumed only Pure Water		
(1) 60 lb	3 2 grm	1/10000
(2) 43	2 05 „	1/10439
(3) 65 ,	3 2 ,	1/10100
II —Batch X—six in number—which Consumed only Fæcally Contaminated Water		
(1) 48½ lb	3 6 grm	1/6654
(2) 26½ ,	2 93 „	1/4500
(3) 38 ,	2 3	1/8000
(4) 30 ,	1 5 ,	1/10000
(5) 22½ ,	2 32 „	1/4800
(6) 29 „	1 35 ,	1/10700
III —Batch Y—seven in number—which Consumed Fæcally Contaminated Water as in the Case of Batch X, together with the Excrementitious Products of Earthworms		
(1) 50½ lb	4 0 grm	1/7000
(2) 41½ „	4 3 ,	1/4850
(3) 56 „	3 7 ,	1/7530
(4) 55½ „	3 6 ,	1/7700
(5) 49½ ,	5 4	1/4272
(6) 45 „	1 9 ,	1/11700
(7) 39 „	1 9	1 10000

Marked differences were observed in the microscopical appearances of the thyroid in these animals In the control animals the vesicles were found to be small, round, compact, and lined with cubical epithelium The space between the vesicles was filled with masses of rounded cells, and many vesicles were seen in the field of the microscope In the *thyroids of these animals which showed the greatest increase* in size as determined by weight the vesicles were much larger, their walls markedly thinner, and their outline more irregular, while fewer appeared in the field of the micro*scope than in the case of the normal gland* The epithelium lining the vesicles was much flattened and the intravesicular cellular tissue was markedly less in amount than in the case of the normal gland Glands which showed an intermediate degree of enlargement presented in some parts of the section the appearances of normal tissue while in others the dilated vesicles, flattened epithelial lining, and the scarcity of intravesicular cellular tissue were characteristic of the more enlarged organs In short, every degree of variation was met with, from the small, round, compact vesicle of the normal organ to the cyst-like dilatation of the vesicle of the enlarged gland The increase in size of the enlarged thyroid appeared to be due wholly to the distension of the vesicles with colloid material Photomicrographs show these *points of distinction clearly*

For the purpose of comparison I now show you a *photomicrograph of a large* external trout goitre, which is taken from a paper by Marine and Lenhart The large dilated vesicles filled with colloid and the thinning of the vesicle walls are well seen

This experiment proves that an enlargement of the thyroid gland of goats can be induced by infecting the water supply with the fæces of sufferers from goitre It does not amount to proof that the enlargement so induced is due to the action of a specific living excitant of goitre, it might be due only to the organic impurity of the water

In 1911 I repeated this experiment Twelve female goats, aged 2 years, were employed In this case the animals were much better fed their ration consisting of 1 lb of grain and as much lucerne grass as they could eat The experiment was continued for 107 days At the end of this time seven of the animals were taken at random and killed in the manner I have described The *accompanying* table shows the weights of the thyroid glands as compared with the body weight of the animals —

No	Weight of animal	Weight of thyroid	Proportionate weight of thyroid to weight of animal
I	42 lb	2 8 grm	1 7 466
II	42 ,	3 0 ,	1 6 999
III	38 ,	1 3 „	1 14 600
IV	55 „	3 1 „	1 8 800

In three of these animals the thyroid gland was considerably larger than normal The increase in size, however, was not so marked as in the first experiment, a difference which may be attributed to the fact that the animals in the experiment were better fed and gained in weight, whereas those in the first experiment had *lost* in weight. Two animals had thyroid glands below the normal weight, while two showed no marked deviation from the normal size. The histological appearances of the glands of these animals varied very considerably. I shall indicate only the appearances observed in the case of those glands which were above the normal weight (Nos. 1, 2, and 7). Nos. 1 and 2 were identical in appearance. The vesicles were on the whole larger, more irregular in shape, and the total amount of colloid was greater than in the case of the normal gland. The epithelium lining the vesicles was somewhat higher than normal. The thyroid in these cases did not present the same degree of dilatation and irregularity of the vesicles, nor the marked flattening of the epithelium, which was observed as a result of the first experiment. Indeed, apart from the increase in size of the organs, it cannot be said that the histological appearances differed in any marked extent from the normal gland.

The histological appearances of the thyroid gland of goat No. 7 revealed a considerable degree of hyperplasia. The vesicles were small, the amount of colloid comparatively scanty, the lining epithelium was columnar, and the vessels of the gland were dilated. The gland was markedly more cellular than any other in the present experiment.

Experiments on goats were also carried out to test the effect of feeding these animals on cultures of micro-organisms grown from the fæces of goitrous individuals.

Four female goats, aged 2 years, were gives 48-hour cultures on Musgrave's agar of such organisms as grew on this medium after inoculation with the fæces of a goitrous individual. An emulsion of the bacteria present was introduced into the stomach of the animals by means of a funnel every other day for 61 days. At the end of this time a similar emulsion of a spore-bearing bacillus, which had been isolated from the fæces of a goitrous horse, was administered on alternate days for a further period of 47 days. The animals were then killed and their thyroid glands examined microscopically. The accompanying table shows the weight of the thyroid gland in each case relative to the body-weight of the animal:—

No.	Weight of animal on Jan. 20th.	Weight on May 7th.	Increase in weight.	Weight of thyroid.	Proportionate weight of thyroid to body-weight of the animal.
I.	42 lb.	54 lb.	12 lb.	1·0 grm.	1 : 27,000
II.	48 ,,	65 ,,	17 ,,	2·3 ,,	1 : 13,000
III.	37 ,,	40 ,,	3 ,,	2·0 ,,	1 : 10,000
IV.	32 ,,	41 ,,	9 ,,	1·6 ,,	1 : 12,000

It will be observed from the table that:—1. All the animals increased in weight. In No. 2 the increase was very marked. In No. 3, in which the thyroid was of normal weight, the animal increased only 3 lb. in weight. 2. In three cases out of four the thyroid gland was smaller than normal; in No. 1 very markedly so. There was, therefore, in these animals no evidence of any enlargement of the thyroid gland (goitre). But well marked histological changes were observed in all animals in which the thyroid showed considerable deviation from the normal weight. I shall refer only to two of these:—

In No. 1 the vesicles were round or oval, lined with cubical or low columnar epithelium; the colloid was small in amount; a large area of parathyroid-like tissue formed about one-half of the total sectional area of the gland. This area was wholly cellular and showed an absence of colloid. The capillaries and vessels of the stroma were dilated; there was some increase of the connective tissue stroma of the organ, especially around the blood-vessels, the walls of which appeared somewhat thickened.

In No. 2 formed vesicles were almost wholly absent, or were filled with round, imperfectly-staining cells and cellular débris; where vesicles were seen they were lined with irregular, high columnar epithelium, the lining being often incomplete in parts. Stainable colloid, with the exception of a few densely stained particles, was almost wholly absent. The stroma was increased markedly in amount, and formed a network, the meshes of which were filled with round cells and cellular débris. The capillaries of the organ were not noticeably altered. The appearance of the gland, together with the greatly increased weight of the animal (17 lb.) were suggestive of a commencing myxœdema.

The peculiar histological features of these cases find a parallel in some cases of rat goitre, due to the consumption of the Aarau water residue, recently recorded by E. Bircher, which are sufficiently interesting to merit detailed description. One of these cases is that of a young rat which was given the residue mixed with its food for a period of 12 months. The growth of the animal was considered to have been backward. The thyroid gland showed a moderate enlargement about the size of a pea. On section the gland presented the appearance of an irregular frayed network. Microscopically, normal follicular tissue was nowhere to be seen. The nodose hypertrophy, which is said to be so characteristic of rat goitre, was conspicuously absent. There was a pronounced cellular disintegration and desquamation of the epithelium into the lumen of the vesicles. The epithelial lining was incomplete and frayed; the cell nuclei were altered in appearance and in their staining characters. The vesicles were irregular and communicated one with another, forming irregular spaces. The blood-vessels were dilated, and perivesicular hæmorrhages had taken place. Small particles of intensely staining hæmatogenous colloid were present in the vesicles; the colloid was not vacuolated. Many small darkly-staining nuclei were present. The whole presented a picture of a confused cell chaos. Bircher diagnosed the case as one of "struma degenerativa." Similar changes were observed in goitres produced in rats by means of the material separated from the water by the septum of the dialyser. In these also the nodose hypertrophy, characteristic of rat goitre, was absent.

With regard to the defects of growth especially observed in those rats fed on the residue of goitrigenous waters, and on which Bircher lays such stress—having myself seen the conditions under which these animals are kept, conditions which, though by no means bad, are certainly favourable to the development of many diseases other than goitre or cretinism—I feel bound to record my opinion that, in attributing these defects to the specific agent of goitre, Bircher is overlooking other common causes of defective growth.

Coincident with my last experiment, four other female goats were given the same cultures in the same way and for the same length of time, but one hour prior to the administration of the culture a few grains each of the carbonates of lime, magnesium, and sodium were given to the animals. My object in giving them these salts was to ascertain whether the development of goitre was favoured thereby. Three of the four goats were killed at the end of 108 days. The following table shows in each case the weight of the thyroid relative to the body-weight of the animal.

No.	Weight of animal on Jan. 20th.	Weight of animal on May 7th.	Increase in weight.	Weight of thyroid.	Proportionate weight of thyroid to body-weight of the animal.
I.	44½ lb.	55 lb.	10½ lb.	1·5 grm.	1 : 18,200
II.	41 ,,	55 ,,	14 ,,	1·45 ,,	1 : 16,000
III.	37½ ,,	45 ,,	7½ ,,	2·1 ,,	1 : 10,630

No. 1 showed on microscopical examination a slight increase in the connective tissue stroma; scanty, darkly staining colloid; vesicles, round or oval, and either filled with cells or lined with a high columnar epithelium. The vessels were dilated. The changes indicated a well-marked hyperplasia. No. 3 was normal in appearance.

In No. 2 the histological appearances were the same, but in this case the vesicles were larger and the cells lining them of a lower columnar type, while the colloid was rather more plentiful. The addition of alkalies in this experiment did not appear to influence the result to any extent.

In short, of 7 animals fed on bacterial cultures, 5 not only failed to exhibit any enlargement of the thyroid gland, but were found to show an actual diminution in the size of the organ. On the other hand, 4 of these 5 glands showed a marked hyperplasia.

Four other goats were given the salts of lime, magnesium, and soda for the same period of time as in the previous experiment. Two of these animals were killed. The thyroid glands were of about normal size. One of these on microscopical examination showed also some signs of hyperplasia.

These experiments may be summed up as follows. In animals which drank only water highly polluted by fæces for *periods up to 108 days there was a tendency on the part of the* thyroid to be larger than normal, and to exhibit on microscopical examination an increase in size of the vesicles, irregularity and thinning of their walls, and distension of the vesicles with colloid; in animals which were fed on cultures of bacteria for the same length of time there was a tendency on the part of the thyroid gland to be smaller than normal, while the histological appearances of the organ were those of an active hyperplasia, often very pronounced. I think it possible that future investigations will show that this apparent difference of result is nothing more than a different stage in the process of development of goitre.

Of the experiments with bacterial cultures the two most striking results are the marke[illegible] panying diminution in size of [illegible] in conformity with that produc[illegible] recently Farrant, as a result of the injection into animals of bacterial toxins; the diminution in size has been noted by other experimenters. Edmunds found in one of his dogs in which partial thyroidectomy had been performed that the remaining lobe, though it showed marked hyperplasia on microscopical examination, was macroscopically smaller than normal. Farrant also has concluded that the earliest stages of hyperplasia are associated with a diminution in size rather than an increase.

It remains only briefly to contrast these results with the histological changes apparent in the goitres artificially produced by Bircher and the Swiss Goitre Commission. Bircher was good enough to give me an opportunity of examining his specimens in his laboratory at Aarau. Undoubtedly pronounced changes had taken place in the glands, but these changes, in my opinion, generally bore a closer resemblance to those usual in exophthalmic goitre rather than those which we are accustomed to expect in simple goitre. Papillary outgrowths of the alveolar walls, for example, were very marked, while the distension of vesicles with imprisoned colloid was rarely noticeable. Branchings and ramifications of the alveoli were frequent. Moreover, in two sections I observed considerable blood effusion into the substance of the gland, a fact for which I can offer no explanation.

Professor Langhans very kindly gave me in Berne a manuscript report of the histological changes which he had observed in the rat goitres, produced by the Swiss Goitre Commission as a result of seven months' feeding on Lauterbrunnen water; at the same time I was permitted to see the specimens themselves. Briefly summarised, Langhans's observations show that there occurred no new formation of follicles, no branching of the alveoli, no characteristic nuclear changes. He has noted degenerative processes proportionate to the period of exposure to goitrous influences, desquamation of the epithelium lining the vesicles, and increase in volume of the protoplasm. The nucleus he found to lie near the base of the cell "very eccentrically placed," but he observed none of the alterations in structure described as not infrequent by Bircher. The alveoli were mostly filled with desquamated cells.

Histological research, therefore, has established the fact that marked changes occur, and has provided a description of several, but further experiments are necessary to establish the sequence of these changes, their interdependence on one another, and their bearing on the etiology of the disease.

CONCLUSION.

Gentlemen, I have concluded my argument. I have endeavoured to put as succinctly as possible the ascertained facts and the logical conclusions whereon is based my belief that the *essential cause of endemic goitre is a micro-organism* that finds its home in the intestines of man, and there creates a toxin which so influences the thyroid gland that it undergoes the enlargement which is the dominant symptom of the infection. In searching the existing literature on the subject I have endeavoured to omit no observation and to pass by no fact that appeared to merit attention, and I have been careful to set down as a fact within my personal knowledge nothing which I have not satisfied myself to be accurately true. Nor have I attempted to propound deductions without setting forth the premises from which I believe them to result.

I am, however, well aware of, and I have been at some pains to explain, the incompleteness of our present knowledge of the facts essential to a final determination of the etiology of goitre. As we have passed from stage to stage in our argument suggestions have arisen and side issues been aroused, each of which still offers a field of fruitful promise to the investigator, and any of which may bring to light fresh facts that may cause us eventually to modify the belief which, to my mind, the evidence at present before us justifies.

It is impossible to consider the parasitic thyroiditis described by Dr. Carlos Chagas, or the ingenious methods by which Dr. Bayon has produced enlargements of the thyroid gland, without being impressed with the possibility that in the near future we shall have to recognise several distinct causes of endemic thyroidomegaly—and therefore several distinct diseases of the thyroid gland—of which the endemic goitre we have been discussing is, in fact, but one. But of this at least there can be no doubt: to the disease which we have been investigating, with its widespread prevalence and appalling consequences, can be attributed no small fraction of the sum-total of human suffering, and incomplete as our knowledge of its causation is, we know enough to make it certain that good sanitation, cleanly houses, cleanly food, and the provision of water-supplies which are not fouled by the excreta of man and beast are measures which promise an extermination of the disease.

ADDENDUM (*Jan. 3rd, 1913*).

In a comprehensive paper on the etiology of endemic goitre, published within the last few days,[3] E. Bircher refers to an extensive series of experiments which have lately been carried out by Sazuki, under the direction of Professor Wilms, of Heidelberg, with a view to studying the action of organic poisons in the production of goitre.

These experiments, as quoted by Bircher, are as follows:—1. By feeding animals (rats?) on cooked rice mixed with rat fæces and by the subcutaneous injection of rat fæces *moderate-sized enlargements of the thyroid gland* of a diffuse form were produced. 2. Feeding with decayed fish. Negative result. The animals showed disturbances of growth and died rapidly. 3. Feeding with decayed meat. Negative result. 4. Feeding with calf's thymus. Negative result. 5. Subcutaneous injection of the dead body in small and large doses gave negative results. The animals (so treated) soon died. 6. Subcutaneous injections of tyrosin gave negative results. 7. Subcutaneous injections of acetonitrile yielded negative results. 8. Feeding with rat fæces mixed with iodide of potassium yielded negative results. 9. Feeding with rat fæces mixed with thyroidin yielded negative results.

Commenting on these results Bircher says: "These different experiments show that though the organic poisons are not capable of producing goitre, yet the feeding and subcutaneous injection of fæcal matter can lead to goitrous changes, as has already been shown by McCarrison; and, further, that iodine preparations, such as potassium iodide and thyroidin, are capable of exercising a restraining influence on the formation of goitre."

This confirmation of my experiments by Wilms and Sazuki lends further striking support to my contention that the excitant of the disease is resident in the intestinal tract.

---

THE BROMPTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.—The next special post-graduate course in the Diagnosis and Treatment of Pulmonary Tuberculosis at this hospital will commence on March 3rd, and will continue for a fortnight. Each morning there will be demonstrations and practical work in the laboratory, and each afternoon there will be clinical demonstrations in the general and special out-patient departments and in the wards. In connexion with the course a series of public lectures will be given at 4.30 P.M., and on Friday, March 14th, there will be an expedition to the Frimley Sanatorium. The syllabus of the course, the list of lecturers, and other particulars, may be obtained on application to the Dean at the hospital.

A Clinical Lecture
ON
TUMOURS OF THE KIDNEY.

Delivered at the Cancer Hospital, Brompton, on Jan. 29th, 1913,

BY R. H. JOCELYN SWAN, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO THE HOSPITAL.

GENTLEMEN,—In the series of lectures which are to be given at this hospital it is our object to make them as much a clinical demonstration as possible, and though we may of necessity refer to the work of others in each subject, we shall illustrate our remarks by reference to cases in the hospital as well as by showing numerous pathological specimens and microscopic sections prepared from them.

This afternoon I propose to speak on the subject of Tumours of the Kidney, under which title I wish to include any form of growth arising in the renal tissues, excluding any fluid or cystic swelling of the kidney, such as a hydronephrosis or pyonephrosis. For this purpose I have collected 12 cases, 10 of which have occurred in my own practice and the remaining 2 in that of my colleagues in the hospital. In addition I have two specimens which were found in the course of an autopsy.

VARIETIES OF RENAL GROWTHS.

There are several varieties of growths found in the kidney, and in recent years a great deal of pathological work has been carried out upon them. A very great deal has been written upon the subject, and several theories as to the origin of these tumours have been brought forward, so that much confusion has arisen as to their true nature. This is particularly true with regard to the most common form of malignant tumour of the kidney—namely, the hypernephroma; and I shall again refer to the discussion that has taken place when I deal with the pathology of this tumour. Of the growths which affect the kidney, a division must be drawn between those which arise in the renal parenchyma and those of the renal pelvis, and the best classification is that given by Garceau.[1]

A. Solid tumours of the renal parenchyma.
- *Malignant.*—(1) Hypernephroma; (2) carcinoma; (3) sarcoma.
- *Benign.*—(1) Adenoma, (2) angioma, (3) lipoma; (4) fibroma.
- *Embryonic tumours.*—(1) Dermoid; (2) rhabdomyoma; (3) mixed tumours.

B. Tumours of the renal pelvis.—(1) Papilloma; (2) villous-covered carcinoma; (3) epithelioma.

The hypernephromata are by far the most common form of malignant tumour of the kidney, occurring in from 75 to 80 per cent. of all renal tumours. The pathology of this tumour was first brought into prominence by Grawitz[2] in 1883, who described it as arising from the small masses of aberrant adrenal tissue which are frequently found in the cortical portion of the kidney. These tumours arise in the cortical portion of the kidney, forming rounded masses with a capsule formed of condensed renal tissue; they tend to spread towards the renal pelvis, which they ultimately invade and also may gain entrance into the renal vein or even the inferior vena cava. On section a hypernephroma varies considerably. It may be of firm consistence, but frequently shows areas of necrosis and softening, and most commonly some dark areas into which hæmorrhage has taken place. One marked feature which is present in almost all cases is the presence in the tumour of small areas of a fairly bright yellow colour. These changes are well shown in the different specimens which I have collected, hæmorrhage and a certain amount of necrosis being present in nearly all of them.

On microscopic section the growth exhibits a structure which reminds one, at first sight, of the normal suprarenal. The cells are arranged in palisade form, large, of polygonal shape, and with well-marked cell walls. The protoplasm is clear and contains highly refractile bodies, and is found to contain both fat and glycogen. It was the close resemblance of the cells of this tumour to those of the suprarenal capsule which led Grawitz to believe that hypernephromata arose from the aberrant suprarenal rests in the kidney; this view found many supporters, and much discussion arose as to whether the tumours should be classified as carcinoma or sarcoma. At the same time, it should be said, the suprarenal rest origin has not been accepted by all pathologists, and it has been recently held by Stoerk and by Shaw Dunn[3] that these tumours arise in the renal tissues, especially in cirrhotic kidneys, and are thus true renal carcinomata. Whilst so much uncertainty remains as to the nature of these tumours it is as well to adopt the name hypernephroma suggested by Lubarsch.[4]

In connexion with the origin of these tumours we have a specimen (Fig. 1) in our museum which was found by Dr. E. H. Kettle in the course of a post-mortem examination upon a case of epithelioma of the tongue. Embedded in the medullary portion of a cirrhotic kidney is a small yellow tumour of the size of a large pea, which shows on microscopic section the typical appearance of a Grawitzian tumour, a tumour so small that it had produced no symptoms during life, but which is of great pathological interest.

Hypernephroma is disseminated by direct extension or by metastatic deposit. If the growth reaches the renal vein emboli may find their way to the lungs, &c., and deposits are most frequently found in the lungs, the liver, or in the bones.

Primary carcinoma is a much more rare form of malignant tumour of the kidney than hypernephroma, and in this hospital we have only one specimen of it. Previously a large number of tumours were classified as carcinomata which, upon further examination, prove to be hypernephromata, so that the tables given in the various text-books are quite unreliable. Several well-authenticated cases of true carcinoma are recorded, but probably they do not amount to more than 2 per cent. of renal tumours. The growth appears rapidly to invade the renal pelvis and so gives rise to persistent hæmaturia. On microscopic section the growth shows similar alveolar arrangement to carcinoma elsewhere in the body.

Sarcoma of the kidney occurs as a primary tumour both in the round and spindle-celled variety. It may attack the kidney in late adult life, but is more commonly a tumour of early years—occurring in quite young children. We have one example here removed from a child aged 7 months by my colleague Mr. Howell Evans, which you see in this specimen is a greyish tumour occupying almost the whole kidney. The growth may commence in the capsule or in the tissues of the hilum, rapidly spreading and invading the kidney.

The *innocent tumours of the kidney* very rarely give rise to symptoms during life unless they attain a large size. Adenoma of a papillary or tubular form are frequently found as small cortical tumours of the kidney during a post-mortem examination. The chief interest of them lies in their relationship to carcinoma of the kidney which may arise in them.

Angioma of the kidney is a distinctly rare condition. Recently a form of angioma of the apex of a renal papilla, giving rise to renal hæmaturia, has been described by Hurry Fenwick, but a more rare condition in which a cavernous angioma existed in the kidney as a distinct tumour came under my care in November, 1911.

A young man, aged 19, previously quite well, was surprised to find [illegible] d blood without pain of any [illegible] in spite of complete rest and [illegible] lin under the supposition of [illegible] ler. When I saw him on the third day of the profuse hæmaturia he was blanched, and his pulse small and rapid. A recent specimen of urine was deeply stained with bright red blood and had clotted in the vessel. There was no pain over the suprapubic or renal areas and no other sy [illegible] On cystoscopy I found the bladder to be [illegible] blood was issuing from the left ureteric [illegible] rapidly exposed the left kidney, which [illegible] the outside, but which on section was found to contain a soft tumour of distinct cavernous looking tissue. The organ was removed, and on microscopic examination the tumour proved to be a cavernous angioma. (Fig. 2.)

The specimen has retained its colour admirably, and you will see that the tumour appears to consist of erectile tissue.

Lipomata and fibromata of the kidney are rare. Usually they are quite small, but cases are recorded in which large tumours were found. Clinically they are unimportant.

The *embryonic tumours of the kidney* are comparatively rare. There have been recorded only two cases of dermoid of the kidney (Paget [5] and Haeckel [6]), and some authorities deny the existence of rhabdomyomata occurring in the kidney.

The embryonic mixed tumours of the kidney are those which are composed of both epithelial and connective tissue elements and show a great complexity of structure. There may be striped or smooth muscle fibre, cartilage, bone, together with tubular or glandular epithelial structures. [illegible] rent extent in a tumour, [illegible] that it appears in one [illegible] carcinomatous. These tumours may grow very rapidly and attain a large size, and are apt to undergo myxomatous or degenerative changes. They arise in the substance of the kidney; they do not infiltrate in the same [illegible] to push aside the renal [illegible] organs. Metastases [illegible] first described these tumours as embryonic adeno-sarcomata, and looked upon them as derived from the inclusion in the kidney of elements of the Wolffian body. Wilms,[8] however, suggested that the various elements of a mixed tumour arose from islets of embryonic tissue, but so far there is no *uniformity of opinion as to their origin. The tumours are* found in early childhood, forming a swelling in the loin. They are apparently very malignant.

Of the *tumours of the renal pelvis* the papilloma is the most common. Albarran and Imbert [9] quote a series of 22 cases in which a papilloma commenced in the renal pelvis. The tumours may be multiple and may spread as small tumours along the course of the ureter. The villous-covered carcinoma may occur as a primary tumour or may be a malignant form of a simple papilloma. Macroscopically the growth appears as a papilloma, but the base is infiltrated and has all *the characteristics of carcinoma, spreading by direct continuity* and by metastases.

Epithelioma of the renal pelvis of the squamous-celled variety has been described, and has been thought by Hallé [10] to be secondary to calculous or some other form of pyelitis.

SYMPTOMS.

The symptoms of a renal growth vary to a certain extent with the nature of the tumour present. The hypernephroma is by far the most common form of growth in the kidney, and I shall first speak of the symptoms of this, and later point out the differences in them in the other forms of renal growth.

The three prominent symptoms of hypernephroma are hæmaturia, pain, and the presence of a renal tumour. *Hæmaturia* is perhaps the most important symptom, and immediately attracts the patient's attention. It is frequently the first symptom noticed, and in my own cases occurred as the initial symptom in six out of nine cases. The bleeding commences suddenly without pain, and the patient is surprised to find on micturating that the urine is loaded with blood. Usually the bleeding is fairly profuse and lasts *for several days*, when it may entirely disappear for some weeks, to recur again in exactly the same manner. Bleeding may occur irrespective of any injury or undue exertion, but in one of my cases it distinctly followed any train journey, and in another was produced on several occasions after a long walk. In some cases the urine may contain clots, and I would ask you in all cases in which clots are present to examine them most carefully, especially as to their shape. The best way to do this is to float them *in a large basin of* water, *pouring off* the coloured water and washing the clots until they can be easily seen. If I find *any clots of pyramidal shape*, indicating their *formation in* the renal pelvis, or of a long, round, worm-like appearance, with decolourised ends, from the formation in the ureter, I have little doubt that the bleeding is renal in origin.

Occasionally slight hæmaturia may be present, lasting more or less continuous for some weeks, but in my experience hæmaturia is more frequently of the nature of a recurring profuse hæmorrhage. In the intervals between the bleeding the urine might be quite clear and free from albumin.

Pain in hypernephroma is generally of a dull, aching character referred to the loin in the renal angle—that is, the angle formed by the last rib and the outer border of the erector spinæ muscle—or may extend to the abdomen, iliac fossa, or chest. This aching may precede the onset of hæmaturia, but may occasionally be very severe, similar to the renal colic of a calculus. This severe pain is usually indicative of the passage of a blood-clot down the ureter, when hæmaturia will follow an attack of acute pain, or the attack may be unaccompanied by any hæmaturia. In two of my cases acute pain in the loin described as of a "tearing" nature was present without any accompanying hæmaturia on more than one occasion, and I suspect that this was due to the occurrence of hæmorrhage into the substance of the growth and the resulting increase of intrarenal pressure. It is but rarely that any pain is present on micturition, but occasionally the presence of blood-clot in the bladder may give rise to pain and increased frequency of micturition.

A *tumour* in the loin may be large enough to be noticeable to the patient or may be found upon a clinical examination. In some cases the tumour retains the shape of the kidney, or it may be felt to be nodular or irregular. The lumbar region should be examined bimanually during fairly deep inspiration in the dorsal posture, and if no enlargement of the kidney *is felt* examination should be made in the knee-elbow position, when it may be more easily felt. Occasionally a definite, localised enlargement of the kidney can be felt as in one of my cases (Fig. 3), when a mass *could be felt projecting from the ventral aspect of the kidney* as large as a cricket-ball. In some cases, when the enlargement chiefly affects the upper pole, it may be hidden by the costal arch, when the lower pole may be palpable, apparently low placed but not enlarged.

In one case of a large hypernephroma I was much impressed by a symptom which at the time was new to me, but which I have subsequently seen in another case of renal enlargement—namely, a calculous pyonephrosis. In the case of this large hypernephroma of the right kidney the tumour could not be felt owing to the fact that the anterior *border of the liver descended to a hand's breadth below the* costal margin; dulness was continuous upwards to the level of the fifth rib in the mammary line and to the fourth rib in the mid-axillary line, and caused much doubt as to the nature of the trouble. Owing to the lumbar pain and the occurrence of attacks of profuse hæmaturia, I explored the kidney and found this large growth, which had extended upwards and in its increase had *pushed* the liver forwards and downwards, rotating it upon a horizontal axis. To remove the kidney I had to do a trans- [illegible] growth in the base of the right lung. Here the "dislocation" of the liver prevented even such a large growth from being palpated.

The remaining symptoms of the disease are due in the most part to pressure of the tumour or to metastases. Varicocele is occasionally present, as pointed out by Sir Henry Morris, and is especially significant if it is present in the right side. Dyspnœa may be due to pulmonary invasion, *or a tumour may appear in some part of the skeleton.*

DIFFERENCE IN THE SYMPTOMS BETWEEN HYPERNEPHROMA AND OTHER TUMOURS OF THE KIDNEY.

There are a few points of difference in the symptoms of hypernephroma and other tumours of the kidney which may help in arriving at a diagnosis of the nature of the growth.

Hypernephroma is most common between the ages of 50 and 70, and is of comparatively slow growth; sarcoma is more common in childhood, and forms a rapidly growing tumour with early cachexia. Carcinoma is a disease of later life, gives rise to more pain, and usually to constant hæmaturia; whereas in sarcoma hæmaturia may be absent, and in [illegible] ular [illegible] the [illegible] eous [illegible] than hypernephroma, so that the resulting tumour of the kidney may be more fixed in position.

Embryonic tumours are most common in early life, and usually form a rapidly growing tumour of the kidney. Pain [illegible] ed feature of these [illegible] by pressure upon [illegible] even ascites with [illegible] veins, jaundice, or dyspnœa, may be present.

With tumours of the renal pelvis, hæmaturia is the marked symptom. It may occur in profuse attacks, often painless or giving rise to acute pain if clots are passed down the ureter. The symptoms may be spread over a number of years in the papillomatous growth. The renal tumour may vary in size if the ureter becomes blocked by growth or by blood clot, the increase in size being accompanied by an increase in pain in the affected side and by the absence of blood in the urine. It is of importance to recognise in these cases that a cystoscopic examination may reveal small secondary villous tufts in the bladder in immediate vicinity to the ureteric orifice.

THE DIAGNOSIS OF A TUMOUR IN THE KIDNEY.

In arriving at a diagnosis it must be ascertained (1) that the hæmaturia is of renal origin; and (2) that the tumour in the loin is an enlargement of the kidney.

1. If when the case presents itself there is a combination of renal pain, tumour, and hæmaturia, especially if blood clots of characteristic renal or ureteric shape are present in the urine, there can be little doubt that the bleeding proceeds from the kidney, but frequently a diagnosis has to be made from a single symptom. Constant and even profuse hæmaturia, painless in character, and uninfluenced by exertion, may be caused by both renal and vesical lesions, and I cannot better exemplify this than by mentioning cases in which error has been made.

The case of angioma of the kidney was thought to be one of villous tumour of the bladder, and so also was one of my cases of rapidly growing hypernephroma by well-known physicians, whilst another case was sent to me by the late Dr. J. H. Bryant as a case of carcinoma of the kidney on account of the intermittent profuse hæmaturia with renal enlargement, which I found on cystoscopic examination was in reality a hydronephrosis caused by a villous tumour of the bladder which caused obstruction to the flow of urine from the ureteric orifice. Frequently with vesical bleeding other symptoms, such as increased frequency of micturition or pain during or following the act, are present, but these may be due also to the presence of blood-clot in the bladder, and I cannot urge too strongly the necessity of a thorough cystoscopic examination in these cases. Even if no lesion is found in the bladder, and there is no change in the ureteric orifice suggestive of renal tuberculosis or ureteric calculus, this elimination is useful, whilst frequently blood can be seen to be emitted from one ureteric orifice. It has been urged that a cystoscopic examination is futile in cases of hæmaturia, but this is quite erroneous, and with the present-day modern irrigating cystoscopes sufficient clearness of the medium can usually be obtained to see a blood-stained efflux from a ureteric orifice and will determine not only that the bleeding is renal in origin but will show the side affected.

Renal hæmaturia may be present in other diseases of the kidney than growth. In renal calculus the hæmaturia is usually slight and often influenced by exertion. There is more pain experienced with calculus, and in the urine pus or urinary crystals may be found. Further, a skiagraphic examination will, under favourable conditions, show a fairly defined shadow in contrast to the ill-defined blurring of the renal space in growth.

In renal tuberculosis hæmaturia may be present, but the diagnosis is usually easy. The age of the patient in tuberculosis, usually of early adult life, the increased frequency of micturition, and the presence of pus and tubercle bacilli in the urine, as well as the enlargement of the ureter felt per vaginam or per rectum, and the marked changes in the cystoscopic appearance of the ureteric orifice, are all points in favour of renal tuberculosis.

A simple hydronephrosis may give rise to hæmaturia and may present some difficulty in diagnosis. The varying size of a renal tumour may suggest a hydronephrosis, but may be due to the distension of the kidney with blood in a renal growth; in hydronephrosis the renal swelling is more regular on palpation, is often of long standing, and may give the sensation of fluctuation or thrill. Frequently some cause for the hydronephrosis can be found.

2. In some cases of renal growth hæmaturia may be absent and the patient is seen complaining of a tumour in the loin and pain. In these cases it is necessary to determine that the tumour is really renal in origin and to differentiate it from other tumours in the same situation.

A tumour of the kidney can be felt to descend from under the costal margin on inspiration, can be grasped bimanually, and pushed forward by the posterior hand. It usually retains the shape of the kidney, rounded in front, and with no sharp edge or notch; the colon is often placed in front of the renal tumour, and the area of resonance of the colon in the loin is lost. The swellings which are most likely to be confused with a renal tumour are tumours of the liver or gall-bladder on the right side or of the spleen on the left, an ovarian tumour with a long pedicle, or a malignant growth of the colon. It will suffice to mention these here, as the points in favour of each will be readily recalled.

Finally, it remains to determine the nature of the lesion of the kidney, if the tumour of the loin be diagnosed as of renal origin. A renal enlargement may be due to hydro- or pyonephrosis, to a cystic swelling or to polycystic disease, to tuberculosis, growth, or to hypertrophy of a single kidney, from the absence, destruction, or removal of the other. Hydronephrosis, tuberculosis, and calculous pyonephrosis have already been discussed, but pyocystic disease may give rise to a renal tumour as well as to hæmaturia. In polycystic disease both kidneys are usually enlarged and may reach a very large size. The urine is pale, of low specific gravity, and usually contains albumin. The disease occurs in any age, but there is frequently a considerable atheromatous change in the arteries, and retinal changes may be present. In one case under my care, in a woman aged 65, the right kidney was enlarged to double the size of the left, there was intermittent hæmaturia, but in the intervals the urine was only of specific gravity 1004–1006.

A single kidney is unlikely to be confounded with a renal growth, as, except for slight enlargement, it causes no other symptom unless diseased. A cystoscopic examination or urinary segregation would show that only one kidney was present.

TREATMENT OF RENAL GROWTH.

Before any radical measure can be undertaken to remove a renal growth thorough examination must be conducted to ascertain (1) that no metastases are present and (2) that the other kidney is present and functionally active.

A careful examination should be made of the liver, the thorax, and the osseous system for any sign of metastatic growth and of the abdomen or lower extremities for any sign of obstruction to the large venous trunks, which, if present, would contra-indicate any operation for removal of the growth. Fixation of the renal tumour in the loin would also point to the spread of the disease outside the renal capsule to the perinephric tissues.

The existence of the other kidney may be proved if urine is seen to be emitted from the ureteric orifice of the presumably unaffected side on cystoscopic examination, but this observation alone gives no indication of the functional activity of the organ. This may be done by separating the urine of the two sides by a Luys's segregator or, better, by passing the ureteric catheter into the ureter of the side to be estimated and collecting the urine from that side separately.

In my own practice I not only estimate the urea content of the urine collected, but I make use of one of the colour reagents to test the renal activity. After the catheter has been in position for about half an hour and is found to be acting satisfactorily, I inject 15 minims of a 5 per cent. solution of methylene blue into the gluteal muscles and watch for the first sign of colouration in the urine flowing from the catheter. If the renal function is unimpaired a greenish tint will be found in the urine in 30 minutes, increasing to an emerald green in an hour or an hour and a half after the injection was given. Even in 15–20 minutes after the injection a colourless product may be found in the urine, which may be converted into green by boiling for a few minutes with acetic acid.

If the urea percentage is good and methylene blue is shown present in the urine within 30 minutes there is strong evidence that the remaining kidney is working satisfactorily. The same colour reaction may be carried out with indigo-carmine or the renal activity tested by noting the time of appearance of sugar in the urine after an injection of phloridzin.

If these tests are satisfactory and there are no metastases the only treatment that can hold out any prospect of cure is the removal of the affected kidney. A small tumour enclosed in its capsule of compressed renal tissue which may have given rise to hæmaturia is the most favourable one

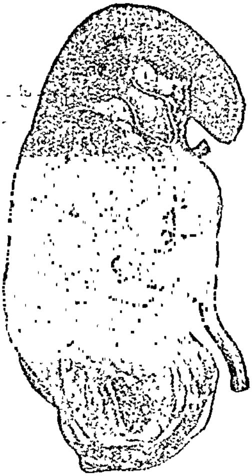
FIG. 6.



Papillary carcinoma of the lower pole of the kidney that the reddish areas seen in the marrow cavities of the bones, which at the post-mortem examination were thought to indicate a hyperplasia of the red bone marrow, were found on microscopical examination to be in large measure due to hæmorrhages.

Liver and kidneys.—These showed nothing of note beyond slight venous congestion and cloudy swelling.

Spleen.—The spleen showed, in addition to the ordinary splenic elements, numerous nucleated red cells, both normoblastic and megaloblastic. Here and there normoblasts were seen lying in apposition, with the nuclei close together, apparently having been recently formed by division. Some of the nuclei showed irregularity of their margins. The "blue-iron" reaction in liver, spleen, and kidneys was negative.

Although this subject receives little or no attention in the text-books, the condition is perhaps not very uncommon, and probably passes unrecognised in the majority of cases. In the paper already published a short *résumé* of the recorded cases is given. Since then Ward[2] has given details of what may have been another case, but unfortunately it was not verified by post-mortem examination. The patient was a woman who had a rapid recurrence of an epithelioma after removal of the left breast. There was a large mass on the sternum giving rise to considerable pain, and there were small nodules in connexion with the second and third ribs. Enlarged glands were present in the right axilla. The red corpuscles numbered 4,760,000 per cubic millimetre and the hæmoglobin was 65 per cent. The colour index was 0·68 and the leucocytes numbered 10,800 per cubic millimetre. There were 382 normoblasts and 104 megaloblasts per cubic millimetre. All the erythroblasts were polychromatophile, and some showed basophile granulation (Giemsa). A differential count of the leucocytes gave 61 per cent. polymorphonucleated neutrophiles, eosinophiles 0·6 per cent., small monomorphs 31·2 per cent., large monomorphs 4·8 per cent., and myelocytes 2·4 per cent. A second case was published in Norway by Professor Peter F. Holst,[3] but we have been unable to obtain this paper.

It would appear from a study of the few cases which have been fully investigated that in most instances the blood shows a strong myeloid reaction, numerous erythroblasts and myelocytes being found. Probably most of the cases in which carcinoma simulated pernicious anæmia closely were cases of metastases in the bone marrow. When anæmia occurs in cancer it is usually of the ordinary secondary type, although erythroblasts are said to be a little more frequent (Da Costa[4]), and a relative lymphocytosis is common (Price Jones[5]). But high colour index, megalocytosis, myelocytosis, and numerous erythroblasts do not occur. Since the publication of the first case one of us (A.W.H.) has investigated this point in 24 cases of malignant disease (chiefly of stomach, pancreas, or bowel), and in no case found it controverted.

It seems to us that a diagnosis of carcinomatous metastases in the bone marrow can be fairly easily made. Most reliance is to be placed on the bone pains and the condition of the blood. In both our two cases the bone pains were very severe, and tenderness was marked. With regard to the blood the points to be laid stress on are high colour index, megalocytosis, and the presence of erythroblasts and myelocytes in considerable numbers. Leucocytosis is common, but seems to be variable. In the case under consideration the number of erythroblasts and myelocytes was small, but the destruction of marrow by the cancer was very complete, and possibly at an earlier stage of the disease these cells may have been present in larger numbers. The leucocyte count was low at first, and this with a moderate relative lymphocytosis made the resemblance to pernicious anæmia closer.

Parmentier and Chabrol[6] lay considerable stress on enlargement of the spleen as an aid to diagnosis, but this was not present in either of our cases. The spleen could not be felt during life, and was not enlarged at the necropsy.

It is a notable point that in many of the published cases the cancer has been of a benign nature locally—pyloric, small, and circumscribed. In the present case, although the tumour extended over a fairly wide area, the great amount of fibrosis in it suggests that its progress was slow. Also there was little in the way of spread to the glands and no involvement of the liver, despite the widely scattered metastases in the bones.

Contrasting the histological characters of the tumours in this case with those of the former, it is interesting to note that in both overgrowth of fibrous tissue was a conspicuous feature in the primary and secondary growths. In the case first published colloid degeneration was observed in many of the cancer cells in the primary tumour, but not in those of secondary deposits. In the present case no colloid degeneration was seen in the primary growth, but a few of the cells in some of the metastatic tumours showed it.

Much interesting speculation may be indulged in as to the causation of the profound anæmia. Does it depend on defective hæmogenesis or on excessive hæmolysis? The depraved nutrition of the patient plays a large part, and in many cases the effect of repeated small hæmorrhages must be considerable. In the present case there was no gross hæmorrhage, and occult blood was absent from the stools. No evidence of hæmolysis was obtainable. The urine contained no excess of urobilin, and the liver, spleen, and kidney showed no "iron-blue" reaction. But the red bone marrow was practically destroyed by cancer, so that defective hæmogenesis must have played a large part. In what manner the cancer tissue acts upon the bone marrow it is difficult to say. The metastatic growths or their products may at first stimulate the marrow, and later on destroy and replace it. Upon such an assumption the previously published case represented the earlier stage in which the marrow was stimulated, and showed a strong myeloid reaction, while in the present case the extensive destruction of marrow prevented the reaction. The presence of nucleated red cells in the spleen, many of them showing mitosis, is exceedingly interesting, and may be considered as an attempt on the part of the spleen to take up the rôle of blood formation.

In any case of grave anæmia the presence of pains and tenderness of the bones should always arouse suspicion of carcinoma of the bone marrow. If the blood on examination shows characters suggestive of pernicious anæmia, but with an excess of erythroblasts and myelocytes, the diagnosis of metastases in the bone marrow is highly probable. The present case seems to show that even in the absence of evidence of myeloid reaction, if there be any suspicion of carcinoma of the stomach, high grade anæmia, with high colour index and megalocytosis, taken along with the presence of bone pains, renders the diagnosis of bone metastases almost certain.

THE WOMEN'S IMPERIAL HEALTH ASSOCIATION.—The annual meeting of this association was held on Jan. 29th at 7, Hanover-square, London, W., the President, Muriel Viscountess Helmsley, being in the chair. The association had a year of good work to report. Schools for mothers have been started in Lambeth, North Kensington, and Tottenham, and a juvenile health crusade is enlisting children all over the kingdom as soldiers to fight the battle against disease. The antituberculosis play produced at the Court Theatre in November was found to have provoked wide interest, as many requests had been received that it might be performed in the provinces. The difficulty here was the expense involved, but arrangements had been made, it was said, to have a cinematograph film taken which would enable the lessons of the play to reach a much larger audience. The association has continued the caravan tours, and this year Sussex was visited and certain places in Kent and Surrey. The London Parks Caravan worked during the summer at Battersea Park, Clapham Common, Wandsworth Common, and Tooting Common; the London County Council gives special permission for the van to take up its stand in the parks, when a lecture is given which is illustrated by lantern slides and cinematograph pictures thrown on a daylight screen which is hung on the side of the van. During the year 310 lectures have been delivered under the auspices of the association, many of them illustrated by lantern slides and cinematograph films. The treasurer's report was satisfactory, and he was able to point out that economy had been effected in several directions without any decrease in efficiency.

SOME OBSERVATIONS ON A SERIES OF 78 CASES OF STREPTOTHRIX INFECTION.[1]

BY ALEXANDER G R FOULERTON, F R C S ENG,

DIRECTOR OF THE BACTERIOLOGICAL AND CLINICAL PATHOLOGY LABORATORIES AT THE MIDDLESEX HOSPITAL LECTURER ON BACTERIOLOGY TO THE MIDDLESEX HOSPITAL MEDICAL SCHOOL.

BY way of contribution to a discussion upon streptothrix infections I thought that it would be worth while to refer to some points in connexion with a series of cases which have been investigated in my laboratories at the Middlesex Hospital, and in which the presence of the causative parasite has been demonstrated positively by laboratory methods

In the Milroy lectures On the Streptotrichoses and Tuberculosis in February, 1910,[2] I was able to refer to 53 cases of the kind which had been investigated at the Middlesex Hospital during the preceding ten years During the last three years 25 additional cases have been examined—13 cases of primary infection of parts about the mouth and neck, 6 cases of primary infection of the appendix, *5 cases of pulmonary infection and 1 case of cystitis* The series, therefore, now includes 78 cases A very large majority of these have occurred in the routine of hospital work, and material from the remainder has come from cases outside in which I have been consulted If the generally prevailing idea as to the comparative rarity of streptothrix infections were correct, this series of 78 cases investigated in one laboratory during a period of 13 years might seem exceptional, since Acland, who in the year 1884 identified the first case of human actinomycosis recorded in this country, was able to collect only 109 British cases published during the 23 years 1884–1906 But it is certain that, excluding for the time all cases diagnosed as cases of tuberculosis cases of streptotrichosis are much more common than the number of recorded cases would lead one to believe And I am convinced that my own series of 78 cases, observed during 13 years, understates very seriously the frequency of occurrence of cases of streptotrichosis in ordinary hospital practice The series includes only cases in which either a streptothrix was obtained in culture on artificial media, or in which typical branching mycelium was identified in stained specimens of material Had cases in which there were found what were almost certainly rod forms and spores of a streptothrix been included, the list would have been considerably longer The number of cases of appendix infection, for instance, would have been increased largely The question of the microscopic demonstration of streptotrichea will be referred to later on Meanwhile, I may deal with the question as to whether there is otherwise any reason for believing that our results at the Middlesex Hospital are in any way exceptional, in the sense that they do not represent the average of hospital practice

In order to test the value of any special series of cases the best method is that of comparison of the individual result with the collective results of others If the outcome of individual experience coincides nearly with the outcome of collective experience, then the individual experience may be taken fairly as representing the normal average I will therefore collate the Middlesex series of cases with series of cases collected elsewhere by the following tests (1) as to age incidence, (2) as to sex incidence, (3) as to the influence of occupation on incidence, and (4) as to the more frequent sites of primary infection

In the matter of sex incidence the Middlesex series of 78 cases may be compared with one of 405 cases collected by Leith and with Acland s series of 109 cases in which sex is stated in 101[3] It will be seen that the figures of the Middlesex series coincide nearly exactly with Acland s, whilst Leith's figures show a somewhat higher prevalence amongst males

	Number of cases		Sex percentage	
	M	F	M	F
Leith (collected cases)	295	110	72 9	27 1
Acland " "	65	36	65 0	35 0
Middlesex Hospital	51	27	65 4	34 6

In the matter of age incidence the Middlesex cases correspond closely with those of Acland s series The age is stated in 84 of the latter, and was ascertained in 70 of the former

—	Total	Under 15 years	15 years and under 25	25 years and under 35	35 years and under 45	45 years and under 55	55 years and upwards
Acland s collected cases	84	12	24	25	9	7	7
Middlesex cases	70	6	23	19	9	11	2

In Acland s series 49 of the cases, or 58 3 per cent, occurred between the ages 15 and 35 years, in the Middlesex series 42 of the cases or 60 per cent, occurred within the *same age period*

The influence of occupation on the incidence of infection is an interesting subject for consideration in connexion with the pathology of streptotrichosis From the first it has been recognised that infection may be carried to man and lower animals by means of straw and grain That fact was established by clinical observation, it was afterwards found that, when not living as parasites on man and other animals, the streptotrichea are [illegible] the soil, or parasites c [illegible] it is well known that [illegible] e in many ways Koch's *B tuberculosis* occur as natural parasites of grasses and other forms of vegetable life Acland remarks that *"in 17 of the British cases the individual* infected had either been in the habit of chewing straws, ears of corn &c, or had been engaged in agricultural pursuits" An analysis of the histories of the Middlesex series of cases is significant of a probable frequency of transmission of infection to man by various vegetable products Of the 78 individuals included in the series 20 were either occupied with house work or were "unoccupied," and in the case of 18 others the occupation, if any, was not ascertained Of the remaining 40, 2 belonged to the professional class and 38 to the working classes Of the first two one was a medical practitioner, and the other was a woman medical student who died as the result of appendix infection some months after *taking a long summer holiday in the* country During her stay in the country the patient passed every day through a cornfield, and was in the habit of picking grains and chewing them

Of the 38 patients of the working classes, no fewer than 24 were engaged in occupations which brought them into close contact with vegetable products of one kind or another The series includes Coachmen and stablemen, 7, gardeners, 3, bakers, 2 foreman of timber yard, 1, carpenter, 1, greengrocer, 1, dairymaid, 1, cellarman, 1, working tailor or tailoress, 7

The group of 7 working tailors or tailoresses (the latter including 2 dressmakers) is an interesting one in this particular connexion, it *includes 2 male and 5 female patients* who would have been in the habit of constantly passing cotton between their lips Of these the 2 tailors had each a submaxillary abscess, the 3 tailoresses suffered respectively from pulmonary streptotrichosis, acute parotid abscess, and a submaxillary abscess, 1 dressmaker had a submaxillary abscess, and the other died with suppurative thrombosis of the superior mesenteric, splenic and portal veins resulting from appendix infection Of the remaining 14 patients of the working classes one was a young man who lodged in a room over a stable, and another was a working blacksmith and farrier whose occupation would bring him into close contact with horses

Comparison as to site of primary infection in the series of Middlesex cases with that in series of cases collected elsewhere is complicated somewhat except for the pulmonary cases by the fact that the former series comprises mostly cases

---

[2] THE LANCET Feb 26th (p 551) and March 5th (p 626) and 19th (p 769) 1910

[3] I have to express my thanks to Dr Acland who has very kindly provided me with the details of the *109* collected British cases which are referred to in his monograph on Actinomycosis in Allbutt and Rolleston s System of Medicine vol ii Part 1 1906 Dr Acland wishes the full share of Dr P S Hichens of Northampton in the work of compilation of the series to be acknowledged

cases an exact diagnosis on clinical evidence is impossible. After one has excepted cases in which the occurrence of an abscess about the mouth raises suspicion of a possible streptotrichial infection, and advanced cases in which there has been a progressive infection of the subcutaneous tissue with characteristic appearances on the surface, there are no means for the differentiation clinically of streptotrichosis from many other kinds of infection. In pulmonary infections the clinical symptoms and signs are those of chronic phthisis; and it is only the occasional perforation of an intercostal space, with possibly subcutaneous extension of the infection, which may help in differentiating a case from one of pulmonary infection by Koch's parasite. In the latter infection, however, perforation of the chest wall is probably of extremely rare occurrence. And it may be added that in only one of the 14 cases of pulmonary streptotrichosis examined at the hospital was there any suggestion that the disease was other than an ordinary tubercular phthisis, until suspicion was raised by failure to find typical "tubercle bacilli" in the sputum, or until typical mycelial forms of a non-acid-fast streptothrix had been identified in the sputum. Equally, a diagnosis by clinical methods of the specific kind of infection is impossible in acute streptotrichial infection of the appendix, or in any case unless there has been extension to the subcutaneous tissue. In the case of mouth infections, whilst there is nothing characteristic about the local abscesses which form in the cheek or neck, the situation of the swelling, and sometimes the occupation of the patient, may suggest a diagnosis.

And whilst clinical diagnosis as to the special kind of infection is impossible in the majority of cases of streptotrichosis, the difficulties in the way of the positive identification of the parasite by laboratory methods are frequently considerable. These difficulties arise from two sources: in the first place there is the extreme difficulty of obtaining growth of many parasites of this class on artificial media, and in the second place there is the difficulty arising out of the varying morphology of these species of moulds at different phases of their life-cycle. It is now well-recognised that the mycelial, or "ray fungus" form, represents only one of the three forms under which these parasites occur; and this typical mycelium, and the mycelium when in the earlier stages of "fragmentation" it is breaking up into "rod forms," represent the only stage at which the parasite can be recognised positively by microscopic examination. At a later stage of development, when fragmentation of the mycelium is complete, and when sporulation has occurred, the picture is no longer that of a "ray fungus"—all that can be seen in a stained film is a collection of somewhat irregular "bacillary" forms, and spherical spores which exactly resemble the common pus cocci; and both forms stain deeply with Gram's method. The difficulty in practice may be illustrated by reference to what is often found on the examination of the exudation in cases of appendicitis. A film stained by Gram's method shows a dense collection of deeply stained spherical and rod forms, together with, or without, bacillary forms which do not stain by Gram's method and which probably prove on culture to be *B. coli communis*. But in a quite large proportion of such cases growth of either of the Gram-stained organisms cannot be obtained. This failure to obtain growth is, in itself, a reason for suspecting that the spherical forms do not represent cocci, since none of the known Gram-staining pathogenic cocci are difficult of growth on artificial media. Suspicion will be increased by the presence of largish masses of minute Gram-staining particles, which probably represent the débris of degenerated masses of mycelium. But these appearances merely give rise to suspicion; positive identification such as is necessary for statistical purposes is impossible unless definite, branched, mycelial filaments which stain by Gram's method are found, or unless the identity of the parasite is established by culture. And it is for this reason that I believe that cases of infection by streptotricheæ are very frequently overlooked; and this is why it appears probable that our own statistics at the Middlesex Hospital understate the frequency of occurrence of streptotrichoses.

In the case of the acid-fast species the difficulty, without successful culture, is still greater, since their appearance as they occur in morbid material may be identical with that of either branching or plain rod forms of the variety of strains, or species, recognised under the name of *B. tuberculosis*—a difficulty which is readily explainable if it is true that what is ordinarily recognised in clinical practice as tuberculosis includes, in fact, one or more specific varieties of streptotrichosis. The difficulty, and in this particular case its solution, may be illustrated by a comparison of one well-defined species, *Streptothrix eppingeri*, with the common strain of Koch's bacillus. The lesions, those of a grey miliary tuberculosis, produced by either may be identical, both to the naked eye and histologically under microscopic examination. Both micro-organisms stain by Gram's method; both acquire acid-fast staining properties with age, but *B. tuberculosis* earlier and more extensively than the other. But the growth of Eppinger's streptothrix on artificial media is much more rapid than that of the tubercle bacillus, and is of quite different appearance; moreover, its pathogenicity for the rabbit is very much more active—death, with a widespread peritoneal tuberculosis, following within a few days of an intraperitoneal injection.

A NOTE ON REMISSION IN A CASE OF EPILEPSY.

BY D. W. CARMALT JONES, M.A., M.D. OXON.,
ASSISTANT PHYSICIAN, AND DIRECTOR OF THE DEPARTMENT OF
BACTERIO-THERAPEUTICS, WESTMINSTER HOSPITAL.

A GIRL, aged 4 years, attended Westminster Hospital i April, 1910, for epileptic fits, of which she had had three i ten days and had bitten her tongue. The maternal grandfather had had senile fits and had been intemperate i alcohol, but there was no other family history of nervou disease. The child had had no former attacks and no convulsions in babyhood; the only previous illnesses had bee scarlet fever and chicken-pox, both shortly before the onse of fits. No abnormalities were found in the nervous system and the child was not degenerate in type.

In May, 1910, attacks of petit mal developed, and th child became "dazed" for long periods together. She wa treated with potassium bromide in the routine manner, an in the subsequent months fits were recorded as follows 1910.—July: Frequent minor fits. August: Five majo fits; also minor fits. September: Four major fits; mino fits. October: One major fit; constant minor fit November: Three major fits in sleep; very frequent mino fits. December: No major fit; minor fits very frequent 1911.—January: No major fit; no minor fit for four day (the longest period of freedom since the onset); minor fit on other days. February: Three major fits; frequent mino fits.

In March, 1911, the child had pneumonia and was ill fo eight weeks, and, as often happens in acute infections i epileptics, during this time the fits were in abeyance. Ther was some recurrence when the pneumonia was over, bu after convalescence was established the fits complete ceased, and for the following year during which she wa under observation there was no recurrence.

The point of interest in the case is this cessation of fit after pneumonia, which appears to be an uncommon event for the better known English and American writers o epilepsy make no mention of recovery following acut disease. The cessation of fits under these circumstanc raises some interesting points. It occasionally happens tha a chronic disease is apparently cured by an acute one. Th writer is aware of a case of chronic tropical dysentery o some years' standing in a retired officer of the India Medical Service which abruptly ceased after an attack c pneumonia; further, it is well known that trachoma i sometimes cured after erysipelas, and sarcomata have bee observed to shrink after the same infection.

Attempts, sometimes successful, have been made to tur these observations to practical account. The older tex books on ophthalmology mention the deliberate infection c the conjunctiva with pus in the treatment of trachoma, an inoculation with jequirity or its toxin is still occasionall practised. Coley's fluid is a preparation of streptococc and other bacterial toxins used in the treatment of sarcomat If such recoveries, whether natural or induced, are mo than coincidences the facts are exceedingly interestin since they imply that immunity to one infection has arise out of recovery from another, an occurrence of which the accepted theories of immunity offer no explanation

Epilepsy occurs in two types of individuals—the degenerate type and the type otherwise physically normal The former have various stigmata, such as arched palates and simian hands, and the latter are not distinguishable anatomically from healthy persons The degenerate type are always to be regarded as potential epileptics, and any strain may precipitate the attacks, such as physical stress as in campaigning, or acute illnesses Attacks of the exanthemata often immediately precede the onset of fits in persons of this type Also, in epileptics of non degenerate type an attack of one of the acute fevers often appears to be the exciting cause of fits, and in the case under consideration the fits came on after scarlet fever

These cases are not strictly comparable with the former It seems probable, and many neurologists are of opinion, that such fits are due to the scars left by an encephalitis If that is so, the fits following the exanthemata in non degenerate persons are due to an infective condition, and the recovery in this case after another acute disease suggests that the fits may be due less to scars than to chronic infection If a symptom such as epilepsy occurs in a person of normal development after an infective disease, it is a reasonable inference that the fits are infective or post infective in origin ; and if as a consequence of a second acute disease the symptom disappears, some support is given to the probability of its infective nature

This case is of interest as an instance of an unusual event in an epileptic's history, as being suggestive of the infective nature of some kinds of epilepsy, and as being a possible instance of an obscure process of immunity

Wimpole-street, W

A CASE OF OSTEOMALACIA

BY SARAH GRAY, F R C S IREL ,

SURGEON TO NOTTINGHAM HOSPITAL FOR WOMEN

OSTEOMALACIA is rare enough in this country to make this case, perhaps, worthy of record

On June 14th, 1910, the patient, a married woman aged 34, small and severely deformed was carried into the out-patient room of the Nottingham Hospital for Women This was her history Seven years previously, being then "as straight as anybody" and two inches taller than at present, she was married Her first child was born nearly three years later—a girl, three weeks premature, weighing 4½ lb , parturition normal This child is now living and healthy During her pregnancy the patient felt a good deal of back ache, but no deformity was noticed She was able to feed her baby partially for nine months Soon after the confinement, however, obvious curvature of the spine was seen, and weakness and pain in the back increased gradually In 1908 she was treated for some weeks as an in patient of Derby Royal Infirmary Massage and electricity, as well as rest, &c , brought about much improvement for a time Towards the end of December, 1909 the pain and weakness returned, but in February, 1910, she became pregnant She had never miscarried, and there had been no symptoms pointing to syphilis or any other disease except that in 1904, one year after marriage, she had been in bed a fortnight with "bad pains in the inside," supposed to have had some connexion with bad smells This was two years before the birth of her first child

On admission the condition of the patient was pitiable She stood with difficulty, and a combination of severe lordosis with scoliosis made the abdomen extremely prominent There was apparent narrowing of the space between the ischial tuberosities Marked superficial tenderness made all examination difficult She was taken into the hospital for a few weeks for observation and nursing, the diagnosis being osteomalacia On vaginal examination the ischial bones and rami were pressed inward, and the pelvic outlet only admitted two fingers The uterus was high, and pregnant about four and a half months There was marked asymmetry of the pelvis, the left side being the smaller

Pelvimetric measurements taken twice over on July 2nd showed 3 cm (nearly 1½ in) difference between the two sides in the distance from the mid point of the iliac crest to the mid point of the top of the sacrum The inter trochanteric distance was only 24 5 cm , the normal average being 31 cm The anterior interspinous distance was 21 5 cm and the intercristal 27 cm The deformity was therefore not rachitic The conjugate diameters could not be taken accurately, partly because of the deformity of the outlet and partly because of the extreme tenderness of the whole body This was so great that the nurses could not lift the patient with their hands, and even being raised or rolled over in a sheet was painful It was ascertained that the contraction was not chiefly at the pelvic brim and, as the measurements indicated, that the pelvis was oblique with an approach to the triradiate form The bones were not palpably soft in ordinary examination The extreme tenderness was a striking feature of the case, especially as the patient afterward proved not to be neurotic

The patient remained in hospital a few weeks and then, after consultation with my colleagues, I sent her to her home in the country, and to the care of Dr J J Tobin, of Ilkeston, with directions to return early in November for Cæsarean section This, of course, was with the full knowledge and consent of the patient and her husband On Nov 9th labour set in, with strong ineffectual pains I therefore, with the kind assistance of my colleagues, Dr C V Taylor and Dr W R Smith, Dr J Watson giving the anæsthetic, performed a radical operation, first extracting the child (a boy, 3½ lb) and placenta, and then removing the uterus, tubes, and ovaries There was considerable hæmorrhage and the patient was much collapsed at the end of the operation She made an excellent recovery and left the hospital in December

The child lived only three months , but the mother improved steadily, so that in April, 1911 she came to a clinical meeting at the Nottingham Medico-Chirurgical Society, and seemed well pleased with the amount of attention she received Last September, 22 months after the operation, I saw her again She looked well and strong, and though she still stooped a good deal her appearance did not strike one as deformed She said she felt that she held herself more upright as time went on She was doing all her housework The only unsatisfactory point was the existence of a small abdominal hernia which could easily be cured The abdominal walls had been so pendulous and atonic that the hernia did not surprise me

As to the causation of this case I can offer no suggestion The patient is the wife of a well to do working man, and when the disease came on she was living in a healthy district in Derbyshire Except by operation she had no special treatment Nursing, good food, and tonics were, of course given But the cure was obviously due entirely to the operation, which brought about at the same time the cessation of pregnancy and the removal of noxious material from some part of the genital organs

The following measurements, showing certain bony changes, may be regarded as confirming the diagnosis They were taken in exactly the same way, with the assistance of the same sister on each occasion The measurements were made (1) on July 2nd, 1910, and (2) on April 11th, 1911 Distance between iliac crests (1) 27 cm , (2) 25 cm Distance between trochanters (1) 24 5 cm , (2) 23 cm Distance from mid point of iliac crest to mid-point of top of sacrum (1) R , 18 cm , L , 15 cm , (2) same distance each side 14 5 cm The other measurements showed slighter differences

Nottingham

CONGENITAL ABSENCE OF BOTH THUMBS

BY J H SEQUEIRA M D LOND , F R C P LOND , F R C S ENG ,

PHYSICIAN TO THE SKIN DEPARTMENT AND LECTURER ON DERMATOLOGY AT THE LONDON HOSPITAL CONSULTING DERMATOLOGIST TO THE RADIUM INSTITUTE

COMPLETE absence of both thumbs is an exceedingly rare malformation, and the case I now report possesses several points of great interest which render it worthy of a detailed record

The patient, a young Polish Jew, presented himself in the Skin Department of the London Hospital on Dec 19th, 1912, for treatment of a Hunterian chancre He was 19 years of age and he was born without thumbs He was a short, slenderly built man, healthy in all other respects, but, original type in its simpler lock and in a mechanism to allow of one handle being used as a sharp crotchet, as in Freke's instrument. It is uncertain if Grégoire devised this modification, since he never wrote on his own forceps, and Boehmer is the original literary authority. Orme-Lowder forceps: Very short, blades straight, broad, narrower at the free ends, which are 1⅝ inches apart when the handles are closed. The fenestræ are wide. The evidence again is that of contemporaries, because Orme left no writings; Lowder admitted Orme's priority in some manuscript lectures. Kühn wrote the first published description of Orme's forceps in 1783. Mulder, a pupil of Orme and Lowder, published important evidence and sketched their forceps himself. The inventors considered that the wide fenestræ and narrowing of the broad blades near their tips adapted the instrument to the fœtal head. Lowder rejected Orme's leather covering for the handles. Mulder and Kilian differ as to the extent of the leather covering in Orme's forceps. The instrument exhibited seems intermediate, being longer than Orme's and shorter than Lowder's, whilst the handles are lined with leather. There is a misstatement of Kuhn as to appointments held by Orme and Lowder, as there is an absence of evidence in the records of Guy's Hospital that the latter ever held an appointment there. Haighton's forceps are an exaggeration of the main features in the Orme-Lowder type, but there is no description of his forceps in his manuscript lectures. Blundell, Haighton's nephew, notices Orme's and his uncle's forceps in his text-book, ignoring Lowder's. There is some uncertainty about the precise nature of variation in Haighton's instrument. Radford figures it. David Davis designed forceps with even wider fenestræ. Conquest's widely fenestrated forceps had a screw-joint in one handle. Osborn's Forceps: The instrument exhibited corresponds exactly to the drawing in the inventor's "Essays" (1792). A light forceps with relatively slender blades bearing a pelvic curve and broadest at the tips, which are three-quarters of an inch apart when closed. The whole instrument, including the fenestrae, is covered with leather. Mulder's contemporary evidence and Denman's own writings award the priority to Osborn. Denman's forceps were similar but the blades had no pelvic curve. Thynne made the blades proportionately longer according to Mulder; Thynne himself left no description of his modification in the abstract of his lectures.

SECTION OF PSYCHIATRY.

Insanity and the Neuropathic Inheritance.

A MEETING of this section was held on Jan. 28th, Sir GEORGE H. SAVAGE, the President, being in the chair.

Dr. F. W. MOTT read a paper on Insanity and the Neuropathic Inheritance. He said there were individuals born of sound mental and physical stocks that no acquired conditions—e.g., disease, drink, poisons, either engendered within the body or taken from without, head injuries, emotional shock, distress and even profound misery and destitution combined—could render insane. There were others, and these were, in most cases, derived from a neuropathic stock, whose mental equilibrium might be disturbed by any one of these conditions or even without any apparent cause, except the physiological conditions appertaining to the functions of the sexual glands at puberty, during adolescence, the puerperium, lactation, and the climacteric period in women. Between these two extremes one found all gradations of menthlity, from the congenital imbecile and the insane adolescent dement at one end of the scale to the potentially sound mind and body which no combination of acquired conditions could render permanently insane. Every case of insanity should be regarded as a biological problem, and the study resolved itself into the acquirement of a knowledge of what the individual was born with—nature—and what had happened after birth—nurture. The former of these could be ascertained by a study of the ancestral stocks. The neuropathic tendency might be manifested in different members of the stock in different ways. Just as bodily features were transmitted from one generation to another, so was temperament. Special racial and family characters were of later development, therefore were far less fixed, stable, and organised in the nervous system. Galton found that twins developed from one ovum, and therefore identical germ plasm, living in a different environment, remained similar in temperament and character; whilst dissimilar twins, brought up and living in the same environment, remained dissimilar. Galton also made a statistical inquiry into the inheritance of good and bad tempers; and concluded that one set of influences tended to mix good and bad at haphazard, another tended to assimilate them, another tended to divide families into contracted portions; and in that way there was a tendency to revert to the normal average of the race. Morel had pointed out that nervous, irritable weakness and neurasthenic predisposition might be the first evidence of degeneration of a stock. The signs of degeneracy might be manifested as self-centred narrow-mindedness in religious beliefs, fanaticism, mysticism, spiritism, and unwholesome contempt of traditional custom, social usages, and morality, a vain spirit of spurious art and culture, a false, self-loving vanity in the pursuit of a sentimental altruism, the intelligence being well preserved. Such qualities might be combined with latent or active genius; but the brilliant intellectual qualities of a degenerate were generally associated with either a lack of moral sense or of sound judgment and higher control. Dr. Mott declared that the world's history had been made by men who were either epileptics, insane, or born of a neuropathic stock: Alexander the Great, Julius Cæsar, Napoleon, Peter the Great, Frederick the Great, Pitt, Earl of Chatham, Mahomet, the Apostle Paul, Martin Luther, Emmanuel Swedenborg, and others. Among English poets, Cowper, Wordsworth, Byron, Gray, Burns, Chatterton, Thompson were either insane or possessed the neuropathic temperament. Dr. Mott then proceeded to describe the work which had been done in the pathological laboratories of the London county asylums on heredity in relation to insanity, chiefly by means of a card system which he instituted four years ago, the cases inquired into having reached 3118, concerning 1450 families. That showed the following facts: (1) In the insane offspring of insane parents daughters were much more numerous than sons; (2) amongst the insane members of the same family (brothers and sisters) sisters were more numerous than brothers, which fact might be usefully correlated with the further fact that there were more women in asylums than men. More than half the residents of the London county lunatic asylums had been secluded there more than ten years. Among the reasons for the preponderance of women inmates were that general paralysis, which was three times more frequent in men than in women, was a fatal disease; again, women were more likely to be insane because of the physiological emergencies connected with reproduction; moreover, women had a more unstable nervous system or mental equilibrium. To those factors must be added, in his opinion, the enforced suppression, by modern social conditions, of the reproductive functions and the maternal instinct in women of emotional temperament. Dr. Mott then proceeded to establish the principle of anticipation or antedating, and nature's means of mending or ending degenerate stock, showing a number of pedigrees, one of which exhibited the elimination of unsound elements in a stock in which there was a dual insane inheritance. It was generally admitted that in the pedigrees of general paralysis of the insane the neuropathic taint was not found to anything like the extent that it was in the pedigrees of patients suffering from neuroses, psychoses, and feeble-mindedness. This was not surprising, seeing that general paralysis was an organic disease due to the action of the syphilitic organism. He had been able to support his contentions by the investigation of upwards of 3000 relatives of persons admitted into the London county asylums.

Dr. E M. WHITE demonstrated a number of very instructive Pedigree Charts and the manner in which the data were ascertained. It seemed to be the general rule that the abnormality on the mother's side was greater than that on the father's side.

The PRESIDENT referred to some cases within his experience in which a man, after a head injury, slowly became weak-minded, and the children, begotten after it, were also weak-minded. He also spoke of the alternation of neuroses, gout or [illegible] insanity in several cases he had s [illegible] insanity were said to behave in t [illegible] sometimes had insane or epileptic offspring. Marriage between offspring of degenerate parents was not such a serious matter where the contracting parties did not themselves show a neurotic taint as where that did exist This presence or abs[illegible] into the question of [illegible]

Dr. ROBERT JONE[illegible] general paralysis, and found that in 28 per cent there was a history of paralysis of some kind in the progenitors, in some of whom it was called "spinal paralysis"; he knew it was general paralysis in some. And there was a history of some member having been insane in 38 per cent; while in 18 per cent. there was a history of drink in the parents. 12 per cent gave a history of epilepsy, and 31 per cent a history of tuberculosis. He considered that disorders of the ductless glands were responsible for much insanity. He believed in the transmissibility of general paralysis of the insane.

Dr. T. B. HYSLOP pointed out the protean character of conditions grouped as insanity, and the fact that in some cases the condition was due to a gross physical defect, such as in the thyroid gland; and he counselled caution in applying Dr. Mott's statistics in too sweeping a manner.

MEDICAL SOCIETY OF LONDON.

Exhibition of Clinical Cases and Pathological Specimens

A MEETING of this society was held on Jan. 27th, Sir WILLIAM WATSON CHEYNE, the President, being in the chair.

Dr. F. PARKES WEBER showed a case of Splenic Anæmia. The patient, a pale, dark-skinned woman, aged 30 years, was admitted under his care at the German Hospital on Oct. 16th, 1912, with chronic enlargement of the spleen and a leucopenic type of anæmia. Under treatment (with occasional intermissions) by arsenic—Fowler's solution, arsacetin, and finally neosalvarsan—the spleen had diminished in size, the anæmia had almost vanished, the patient had gained in body-weight, the menstrual flow had increased, and there had been a subjective sense of improvement. The conjunctivæ had lost their previously yellowish tinge, and the urine no longer gave the reactions for excess of urobilin and for urobilinogen which were at first present. The blood plasma was of medium yellow colour and apparently free from bilirubin There was perhaps, very slightly increased fragility of the red blood cells towards hypotonic salt solutions, hæmolysis taking place partially with 0·45, and completely with 0 4 per cent aqueous solutions of sodium chloride. Wassermann's reaction negative. Dr. Parkes Weber believed that the case was one of a clinical group of cases of "splenic anæmia" in adults which improve under [illegible] necessarily develop into typic[illegible] with hepatic cirrhosis and ascites. The existence of this group of "splenic anæmia" cases must be taken into consideration when estimating the results of the operation of splenectomy in *early* cases of "Banti's disease." As in cases of so-called "acquired chronic acholuric jaundice" with anæmia and splenomegaly, cases like the present one might (at all events, temporarily) show a subicteric tinge of the conjunctivæ, some excess of urobilin in the urine, and slightly increased fragility of the red blood corpuscles [illegible]utions.

[illegible] showed a case illustrating a [illegible] Acholuric Jaundice. It was probably a case of tertiary visceral syphilis with pyrexia and extreme cachexia The patient was shown by Dr Weber at the Medical Society of London on Feb 8th, 1909, as "a case of acquired chronic acholuric jaundice with a blood picture at one time resembling that of pernicious anæmia" Examination of her blood on Jan. 31st, 1908, had given the following result.—Hæmoglobin (by Haldane's method), 18 per cent of the normal; red cells only 900 000 in the cubic millimetre of blood; white corpuscles, 6000; colour index, 1. The differential count of the white cells gave:—Lymphocytes, 45 6 per cent; intermediates, 4 8 per cent; large hyalines, 2 4; neutrophile polymorphonuclears, 46 0; eosinophiles, 0·8, mast cells, 0 4 During the count of 500 white cells Dr. A E. Boycott saw no ordinary [illegible] blasts) of [illegible] red cells, [illegible] to their [illegible] matophilic red cells and many punctate basophilic red cells. Decided anisocytosis and poikilocytosis were present, as in pernicious anæmia The blood picture at that time was one of typical "megaloblastic degeneration," but a striking feature was the association of chronic acholuric jaundice, and the case likewise differed from pernicious anæmia in regard to the enlargement of the spleen and liver. The liver extended two or three fingerbreadths below the ribs, and the spleen, which was hard, reached almost to the anterior superior iliac spine In the treatment of the case the arsenical preparation known as atoxyl was especially employed, but the great improvement which ultimately followed could not with certainty be attributed to the atoxyl, as the period of the most decided improvement commenced a considerable time after the atoxyl treatment had been discontinued. In December, 1908, the blood showed nothing abnormal beyond slight anæmia Since that time the condition had remained fairly good, and the patient had been able to do ordinary household work On July 17th, 1911, the red cells numbered 5,330,000 to the cubic millimetre of blood When exhibited the patient was suffering from interstitial keratitis of the right eye This commenced about June, 1912, and was evidently regarded at an eye hospital as of syphilitic origin, for she was given an injec[illegible] and the reaction for urobilin in the urine was *positive.* The case certainly confirmed the remarks of Dr G R Ward and other observers on the uncertain prognostic value (when considered by itself) of the blood-picture of the so-called "megaloblastic degeneration," which was at one time regarded as pathognomonic of pernicious anæmia As to the cause and real nature of the severe and long-continued illness in 1908 there was still considerable doubt. Was acquired chronic acholuric jaundice with splenic enlargement and severe anæmia (like that from which this patient sufferdd) an independent disease of unknown etiology, or was it merely a clinical picture-type or symptom complex, which might be due to various causes? In this connexion it was important to note that the patient's blood serum now (January, 1913) gave a positive Wassermann's reaction for syphilis and that she was suffering from interstitial keratitis. [illegible] syphilis might indeed occasionally give rise to an [illegible]aracterised by enlargement [illegible]npanied by general cachexia and anæmia, from all of which symptoms this patient suffered in 1908 In all probability the entire illness of 1908 was of tertiary syphilitic origin The atoxyl treatment in 1908 might, like the modern salvarsan treatment, though to a lesser extent, have exercised a decided anti-syphilitic effect

Dr J L BUNCH showed a case of Lupus Erythematosus in a girl aged 14, which demonstrated the good effects of treatment by carbon dioxide snow; and also a case of [illegible] resembling Tubercle in the neck and upper [illegible]n She had been treated by [illegible] or tuberculous glands in the [illegible] other small swellings in the same region, had treated herself in the same way. When first seen by Dr. Bunch a large ulcerated patch had resulted. This healed quickly under treated by potassium iodide internally

Mr. PAUL B ROTH showed a patient on whom he had successfully performed Transperitoneal Ureterolithotomy He said that in January, 1910, Mr Sinclair White had published[1] a paper on Ureteral Calculi, and gave notes of two successful cases of transperitoneal uretero-lithotomy His description of the operation was so clear, and the arguments which he advanced in its favour were so convincing, that he (Mr Roth) determined to perform the operation on the first suitable case, which was the boy now shown. The patient, aged 8, was examined on Sept. 17th, 1912. He looked ill and delicate, and was said to have suffered from pain on passing urine for 18 months, the pain being felt over the lower abdomen, and occurring always at the beginning of the act On four occasions in the urine there had been dark blood, which had covered the bottom of the chamber, the last occasion being three months previously. On these occasions there had been increased pain. There was apparently no increased frequency of micturition. Examination of the abdomen and of a specimen of the urine revealed nothing abnormal. A diagnosis of stone in the bladder was made. A week later the bladder was sounded under an anæsthetic, but no stone was felt. On Sept. 29th an X ray examination was carried out by Dr. W. Ironside Bruce, which showed the outline of the left kidney increased in size, and in the line of the left ureter about 3 inches from its vesical end, a small oval-shaped opacity suggesting an impacted ureteric calculus. Both those points were well demonstrated in radiograms. The boy was kept under observation, and on Nov. 8th he again passed some blood in the urine; it lasted slightly for two days. On this occasion there was no pain, but he felt "irritation of his privates." Operation was then decided upon, and was performed on Nov. 25th. After again sounding the bladder with negative result the patient was placed in the Trendelenburg position, and the lower abdomen opened by a vertical incision through the left rectus sheath. The intestines were packed out of the way with gauze and the rectum pushed over to the right. On introducing the fingers the stone was at once felt on the left side 1½ inches below the brim of the pelvis and apparently the same distance from the bladder. The left ureter appeared beneath the peritoneum as large as a piece of small intestine. As all attempts to push the stone up to the brim of the pelvis failed, the parietal peritoneum was incised above and the ureter isolated. A temporary ligature was placed round the proximal portion and the ureter itself raised up and packed round with gauze. A vertical incision was then made in it on its anterior aspect, about a drachm of urine escaping; a long-necked spoon was introduced, and at the second attempt the stone was dislodged and delivered through the opening. A probe was passed down to the bladder and up to the kidney, and, all being clear, the wound in the ureter was closed with four catgut Lembert sutures. The temporary ligature was removed and the divided peritoneum brought together over the ureter; the abdomen was closed without a drain. The operation lasted 50 minutes. In addition to the enormous hypertrophy and dilatation of the whole ureter there were marked thickening and induration of that part of it which had been occupied by the stone. Mr. Roth said it would have been better to have twisted the isolated ureter round and incised it on its posterior aspect; also the incision need not have been nearly so long. Neglect of these points might account for slight symptoms of peritonitis which occurred on the following day, the temperature rising to 100° F. and the abdomen becoming moderately distended. This latter was entirely relieved by a small soap-and-water enema, and the boy made an uninterrupted recovery. The wound healed by first intention, the stitches being removed on the tenth day. The stone was oval in shape, its diameters being 5/16ths and 7/16ths of an inch; it was composed of small, sparkling oxalate (?) crystals, which caused its external surface to be very rough and jagged. The extreme ease with which the operation was performed had led him to bring it to the notice of the society.

---

[1] Brit. Med. Jour., Jan. 1st, 1910.

Mr. W. H. CLAYTON-GREENE showed a specimen of Hairball removed from the stomach. The patient, a young woman aged 23, had suffered from abdominal pain and vomiting, and a tumour had been felt in the upper part of the abdomen. A radiogram favoured the view that the swelling was gastric. By operation a large hairball was removed, which formed a cast of the stomach and duodenum. Another smaller portion was free in the stomach. Most of the hair was dark like her own, but some was fairer. After the operation it was first noticed that she was wearing a wig.

Mr. CLAYTON-GREENE also showed a specimen of a Peculiar Appendix. It formed a large cystic swelling in the right iliac region, which was removed together with small adjoining portions of the ileum and colon by operation. Subsequently it proved by naked-eye and microscopical examination to be a large mucocele of the appendix.

Dr. FREDERICK LANGMEAD exhibited the Suprarenal Glands removed from a boy, aged 10, who died from Addison's disease. Both glands consisted almost wholly of fibrocaseous tuberculous material. The heart was hypoplastic. It was shown because of the great variety of the disease in childhood.

Dr. T. S. LUKIS showed a case of Acholuric Jaundice in a boy aged 6½ years. He had been pale from birth, but had no jaundice during early infancy. Gastro-intestinal trouble and frequent bronchitis had been present. A tumour on the left side of the abdomen was first noticed by the mother before the child was one year old, and had persisted ever since. Jaundice was first noticed on Nov. 18th, 1911. He had been ill for four weeks, with pale motions and urine the colour of red ochre, and had been jaundiced on and off ever since. There was no family history of jaundice or splenic anæmia. On admission, Dec. 11th, 1912, the child was very anæmic, weak, and dyspnœic on exertion. The skin and mucous membranes were definitely jaundiced. The urine contained urobilin but no pigments or salts. The motions were normally coloured. The liver reached one finger's breadth below the costal margin. The spleen was markedly enlarged and firm. A blood examination on Dec. 11th showed: Red cells, 1,524,000; hæmoglobin, 25 per cent.; colour index, 0·8; white cells, 13,500; myelocytes, 3 per cent; nucleated red cells, 17 while counting 200 white; reticulated erythrocytes, 20 per cent.; fragility, 0·55. The patient's general condition had much improved under treatment with arsenic. The temperature had frequently been raised to 99·4°F., but never higher except during an attack of tonsillitis. The bowels were obstinately constipated. The Wassermann reaction was negative. A blood examination on Jan. 15th showed: Red cells, 2,200,000; hæmoglobin, 30 per cent.; colour index, 0·7; white cells, 19,700; myelocytes, 2 per cent.; nucleated red cells, 16 while counting 200 white; reticulated red cells, 14·6 per cent.; fragility, 0·55.

Mr. E. C. RAYNER showed, for Mr. C. A. BALLANCE, a case of Bony Tumour of the Femur in which a question arose as to whether the tumour was a simple osteoma or osteo-sarcoma.

LIVERPOOL MEDICAL INSTITUTION.

Fracture of Neck of Femur.—Acute Yellow Atrophy of the Liver.—Carcinoma of the Rectum.

A MEETING of this society was held on Jan. 23rd, Mr. ROBERT JONES, the President, being in the chair.

Mr. RUSHTON PARKER read a note on Fracture of Neck of Femur, and showed specimens from two cases, also lantern slides. One case was from a patient, 82 years of age, who died ten days after the injury. The other patient was 72, and died ten weeks after the injury. The specimen showed true bony union. Mr. Parker said he preferred to treat them on a "Thomas" hip splint, though in some cases the "Thomas" knee splint answered.—The PRESIDENT said the specimens were worthy of attention, as the possibility of bony union was denied. In making the initial diagnosis an injury to the hip which produced eversion of the foot and some loss of power in the leg was quite sufficient. In treating these cases he used extreme abduction of the injured limb. By this means the broken surfaces were turned on to each other, muscular tension was released, and if an angle of 45° were obtained the neck of the femur was fixed against the acetabulum. He reduced displacement by pulley or manual extension, then abducted the limb with the knee flexed. The limb was fixed in a special abduction frame, or where an injury occurred out of reach of apparatus good fixation could be obtained by plaster-of-Paris. Fixation should be kept up for at least two months, usually three months. Massage and passive movements were important; the patient could be trained to move the limb in the abducted position. In cases in which deformity had occurred and the limb was adducted with eversion he forcibly abducted the limb under an anæsthetic and kept it fixed for ten days and then massaged.

Dr. NATHAN RAW read a note on Seven Cases of Acute Yellow Atrophy of the Liver, which demonstrated the relation of the disease to syphilis. Four males of the ages of 23, 15, 40, and 27, and three females, 17, 23, and 26 years of age, all had syphilis. In four of the cases leucin and tyrosin were demonstrated in the urine. In one of the females, a girl aged 17, there was a six months' pregnancy.

Mr. K. W. MONSARRAT read a paper on Carcinoma of the Rectum. He first discussed the question of the extent of operation. He described the result of examination of two specimens derived from abdomino-perineal amputations. In both specimens the extent of intramural infiltration was confined to the neighbourhood of the growth. He did not consider that pathological anatomy imposed the duty of removing a large amount of bowel above the growth. He considered that an inguinal anus was preferable to a sacral or a perineal anus. He then drew attention to the high mortality of the combined operation in males, and considered that this method was not advisable in men unless the general condition of the patient was exceptionally good. On the other hand, the combined operation was the method of choice in women. He had performed the combined operation in one case of low pelvic colon cancer in two stages, but did not consider that this plan was advisable.—Mr. F. T. PAUL said it was 35 years since he had first removed a rectal cancer; and he had found that the growth did not extend far in the length of the bowel. The microscope showed practically no infiltration beyond the naked-eye margin of the growth. The colloid form was of bad prognosis and gave extension in the glands. In the ordinary cancer there was not usually glandular infection, except where the growth involved the margin of the anus. In his experience the formation of a sacral anus had been satisfactory if small and tight, while a perineal anus was unsatisfactory. In the former the gut had a rectangular turn which had a valve action, while the straight gut in the latter allowed incontinence and prolapse. The inguinal anus was good, but he thought the sacral the more satisfactory. He did not consider an abdominal incision necessary. He did not think high and fixed cases, especially if involving the bladder, worth the risk of removal of the growth, especially as cases might live for years after an inguinal colotomy alone.—Mr. R. W. MURRAY thought the radical operation unsatisfactory, and even went so far as to believe these cases were best left alone until a colotomy had to be done. He had seen a large number of cases in Vienna, some of which had been done 14 years ago; when he saw the condition of the artificial anus in the sacral region he had been unfavourably impressed. He thought an inguinal anus the least harmful.—Mr. DAMER HARRISSON and Dr. RAW also took part in the discussion.

EDINBURGH OBSTETRICAL SOCIETY.

Ruptured Primary Ovarian Pregnancy.—Insemination and Parturition.

A MEETING of this society was held on Jan. 8th, Dr. J. HAIG FERGUSON, the President, being in the chair.

Mr. GEORGE L. CHIENE read notes of a case of Ruptured (very early) Primary Ovarian Pregnancy, and demonstrated his remarks with lantern illustrations. Having mentioned the causes of serious ovarian hæmorrhage, he then shortly referred to the literature on ovarian pregnancy. His own case was that of a married woman, aged 34, who was admitted to hospital supposed to be suffering from acute appendicitis, but the symptoms pointed rather to an internal hæmorrhage, and the question of a ruptured ectopic gestation was considered; the menstrual history, however, was perfectly normal. A laparotomy was performed, and, a large quantity of blood having been evacuated, a bulging mass, about the size of a cherry, was observed to be protruding from the uterine end of the right ovary. The ovary was rapidly removed. The patient made a good recovery, soon afterwards again becoming pregnant, and in due course gave birth to a healthy child. The ovary was cut in serial sections. Chorionic villi were present in the blood-clot, but no fœtus was found, nor were there any signs of a corpus luteum, lutein, or decidual cells. The pregnancy was probably either one of 10 or 22 days' duration.—Dr. A. H. F. BARBOUR mentioned a special point of interest—that it occurred at the uterine end of the ovary, otherwise it would have been less distinct if near to the fimbriated end of the tube or adherent to it. Another point was that there was such a very profuse hæmorrhage filling the abdomen with blood.—Dr. F. W. N. HAULTAIN considered the main point of interest was that no bleeding occurred from the uterus. Here there had been no regurgitation of blood down the tube and escaping from the uterus. It was not always the case that symptoms of stoppage of menses or irregular hæmorrhage occurred. He had met several with no symptoms of any kind.—Dr. G. F. B. SIMPSON, Dr. D. BERRY HART, Dr. JAMES RITCHIE, Dr. W. FORDYCE, Mr. E. W. SCOTT CARMICHAEL, Dr. JAMES YOUNG, and the PRESIDENT discussed the paper. All agreed that it was undoubtedly a case of ovarian pregnancy.—Mr. CHIENE replied.

Dr. BERRY HART read a paper on the Duration of the Interval between Insemination and Parturition in Certain Mammals as studied in Biometric Curves, with Special Reference to the Calculation of the Onset of Labour in Human Pregnancy. The statistics of Tessier on ewes, and on cattle by Earl Spencer and Tessier relative to the interval between insemination and parturition were first considered. The statistics in regard to 912 ewes gave a symmetrical narrow probability curve like that of coin-tossing, where 50 are thrown for a certain number of times. In the Tessier-Spencer cases, 1205 in all, the curve was similar but somewhat skew. The late Professor von Winckel gave the statistics in 245 cases where the infants weighed over 4000 grammes, and these also gave a probability curve, but one less narrow and with several freaks; it needed smoothing out. The greatest number of cases lay between the 284th and 288th days reckoned from the first day of the last menstruation. Dr. Berry Hart concluded: 1. These cases gave a probability curve symmetrical in ewes, somewhat skew in cattle, and irregular in the human female so far as yet observed. 2. The initial date of calculation in the human female should be the first day of the last menstruation, and the date of labour would be some time in the fortnight containing the 280th day as its centre. Thus, the date of labour could not be exactly stated, but was only a probability one. 3. Labour in von Winckel's cases was prolonged in some instances to the 334th day, and the whole range lay between the 240th and 334th days. 4 This prolongation of date was usually considered as a prolongation of the duration of pregnancy, but it might be due to fertilisation of the ovum shed at the next period, and this would account for the prolongation in a simple way. 5. Some explained the prolongation as a real extension of the pregnancy, and pointed out that in some of the cases the weight of the infants was much above the average. The evidence as to this was unsatisfactory. 6. There is certainly no exact number of days for the duration of human pregnancy and the probable curve is as yet unknown.—Dr. BARBOUR considered it was quite right to work by mean and not by averages. There was the possibility of having to deal with the impregnation of an ovum before the next menstruation, but there would then be a curve with a double head. Dr. Berry Hart's curves were valuable for the past, but it was questionable whether they were of practical value in making a calculation for the future in any case.—Dr. HAULTAIN considered it quite certain that there were cases of protracted gestation, and that in these cases the child was larger. He instanced a case where a woman in her first pregnancy went 2½ months past her expected time, and the child had to be broken up. The next time her labour, to which he was called, came on about six weeks after the calculated date, and a child was eventually born with much difficulty, weighing 13 lb. 12 oz. Labour was induced on the next occasion two weeks after full time, resulting in a living child weighing 10 lb.—The PRESIDENT alluded to the method of calculating the duration of pregnancies as ten cycles of 28 days each, and less or more according to the menstrual type.—Dr. FORDYCE and Dr. YOUNG spoke on the subject.—Dr. BERRY HART, in reply, said the lesson was that the calculation of the duration of pregnancy was a matter of probability, never an exact thing. The larger infants after what was considered protracted pregnancies might be due to an element of giantism from abnormal function of the pituitary body.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held in the Glasgow Royal Asylum, Gartnavel, on Jan. 17th, Dr. J. Crawford Renton being in the chair.—Dr. Ivy McKenzie showed and described pathological preparations from the following cases:—1. A woman, aged 40, an inmate of the Gartnavel Asylum, suffering from recurrent insanity with symptoms of exophthalmic goitre, leucoderma and bronzing of the skin, auriculo-ventricular tachycardia (230 per minute), and auricular fibrillation. Post-mortem examination showed disease of the thyroid gland and of the upper cervical sympathetic ganglion, and hypertrophy of the medullæ of the suprarenals. 2. A man, aged 40, a dement, who died suddenly in Gartnavel Asylum with symptoms simulating intestinal obstruction, tympanites, fæcal vomiting, &c. Post-mortem examination showed necrosis of the pancreas and necrosis of the mucous membrane of the whole length of the small intestine, with marked congestion of the other coats of the small intestine.—Dr. David Newman read a short paper on Certain Urinary Conditions in Women associated with Frequent or Painful Micturition, and demonstrated with the projectoscope the cystoscopic appearances presented in the early stages of tuberculosis of the bladder and in the various stages of colon bacillus infection of the bladder. He pointed out that one of the slightest forms of colon infection of the bladder is seen frequently in infants and young children as the result of want of cleanliness in changing the child's napkins. The frequency of micturition may not be noticed in infancy, and for years afterwards the child suffers from noctural incontinence, which may persist until puberty or even later.—Dr. J. A. Wilson read a paper on Myopia, a Review of 500 Cases, with Special Reference to their Etiology. From an analysis of his cases he found (1) keratitis as the cause of myopia in 16 per cent.; (2) evidence of heredity in 54·8 per cent.; and (3) cases without opacities and without evidence of heredity in 29·2 per cent. In the hereditary group were 17 cases with opacities; 65 cases showed monocular myopia, largely accounted for by keratitis and by heredity. Lenticular changes were found in quite young people. The evidence regarding near work as a cause was reviewed, and it was pointed out that German school hygiene had not lessened the amount of myopia. It was essentially an enfeeblement, and developed both before and during school years, school work being an industry which was contemporaneous with the manifestations of heredity.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 31st, Dr. J. F. Dobson, the President, being in the chair.—Dr. G. W. Watson opened a discussion on Tuberculin, its place in modern medicine. Remarks were made on the varieties of tuberculin in common use, and the various methods of administration were outlined, with descriptions of the types of case suitable for each method. Dr. Watson was of opinion that the efficacy of tuberculin was so far proved that its use was essential in the proper treatment of most cases of tuberculosis of the lungs. He deplored the tendency under recent legislation to make the treatment of phthisis a specialty, and to give it into the hands of a few, rather than to obtain the skilled and enthusiastic coöperation of the whole of the profession.—Dr. A. Christy Wilson spoke of his experience of Beraneck's tuberculin, and instanced cases in which it had proved of great value.—Dr. A. G. Barrs spoke of the treatment as being still on its trial, and confessed that no convincing example of its usefulness had yet come within his experience.—Dr Dobson spoke of the value of tuberculin in the treatment of cases of surgical tuberculosis He was in favour of the method of administration recommended by Wright —Dr. M. Coplans contributed some interesting information about tuberculosis in animals. —Cases were shown by Dr. J. B Hellier, Mr. A. L. Whitehead, Mr. G. Constable Hayes, Dr. Dobson, Dr. C. Oldfield, Mr. J. A. Coupland, Mr. Michael A. Teale, and Dr. Watson.

HARVEIAN SOCIETY.—A clinical meeting of this society was held at St Mary's Hospital on Jan. 30th. The following cases were shown:—Dr. Sidney P. Phillips: An abdominal case, probably tuberculous —Dr. W. H. Willcox: Two anomalous cases of Exophthalmic Goitre, a case of Chronic Enlargement of Joints resembling Charcot's joints, and a case of Perforating Ulcer of the Foot.—Dr. Reginald H. Miller: Post-pneumonic Fibrosis of the Lung, and a case of Endemic Cretinism 15 years old.—Dr E. G Graham Little: A man with Psoriasis covering his whole body, and a woman with Lichen Planus Hypertrophicus —Mr. V. Z. Cope: A case of Syringomyelia, and a case of Recovery after Rupture of the Jejunum —Dr. William Hill A case of Epithelioma of the Larynx, and a case of Stricture of the Pharynx after swallowing glacial acetic acid with suicidal intent.—Mr C W. G Bryan: A girl with a Sarcoma of the Lower Jaw, and a man with a Large Tumour just above the Ankle of doubtful nature. —Mr. D. C. L. Fitzwilliams: A Fibro-lipoma in a child, and a man with a Large Epithelioma growing rapidly from an old urinary fistula.

Reviews and Notices of Books.

The Evolution of the Vertebrates and their Kin. By W. PATTEN, Ph.D. London: J. and A. Churchill. 1912. Pp. 486. Price 21s. net.

THE views of Dr. Patten, which he has laid before the scientific world in many memoirs of late years, and which are now crystallised in the present volume, have something in common with those of the well-known English physiologist, Dr. W. H. Gaskell, of Cambridge. But there is this essential difference which appears to us to pull down the balance in favour of Dr. Patten, that while Dr. Gaskell demands the loss of the primitive alimentary tube as a part of the digestive system and its conversion into the neural canal of the vertebrate, Dr. Patten requires no such drastic evolutionary change. Dr. Patten, indeed, can arrive at an accurate comparison of the arachnid and vertebrate systems and organs without any such hiatus, and merely demands the exchange of the dorsal for the ventral surface in progression. Thus the old idea of the elder Milne-Edwards and of Geoffroi St. Hilaire is resuscitated in a somewhat unexpected fashion.

We can readily allow so much to Dr. Patten, for many invertebrates, notably certain archaic crustaceans, which are particularly implicated in Dr. Patten's scheme, do habitually swim upon their backs with the nervous system dorsally directed. But when we come to his detailed comparisons and to the general aspect of his scheme of development the same difficulties meet us that have been urged by many morphologists in regard to Dr. Gaskell's ingeniously argued views. It is certain that at the moment there is an almost unanimous consensus of opinion that the derivation of the vertebrate stock in the way suggested in the volume before us is impossible and contrary to all received principles. Nevertheless, those same morphologists are at hopeless variance when it comes to anything alternative. So far Dr. Patten is just in his criticisms, and there is always a trace in his arguments, and for the matter of that in the arguments of his opponents, of the essentially non-scientific kind of controversial method—the method of simple assertion.

It is held, for example, on the one side, that the path of evolution has led from the basal forms and not from the more specialised members of one group of animals to another. Therefore we should derive the vertebrates, say the supporters of this opinion, not from the higher groups of the segmented animals, such as arachnids, but from the lower—that is, from simple, worm-like creatures. Dr. Patten, and with him Dr. Gaskell, takes the reverse view. It must be admitted that the best arguments in the way of close anatomical reasoning have been adduced from this point of view, and Dr. Patten is to be congratulated upon the convinced and convincing way in which he has marshalled and used the actual facts at his disposal. To those of us who have lived long enough to see many "phylogenies" put forward with enthusiasm and die in obscurity and neglect Dr. Patten's attempt will not appear as final. And, indeed, the great difficulty in his way, which is in the way of all such attempts, is the necessary lack of information of crucial anatomical data. No fossil will ever yield certain points which it is essential that we should know. Particularly is this the case with those admittedly mysterious creatures, the ostracoderms, which are the pivot upon which Dr. Patten's reasoning turns. They are palæozoic animals, usually regarded as fishes or quite near to them. To Dr. Patten, however, they are arachnid in nature and at the base of the vertebrate series; but we cannot argue from their bony exterior to their viscera.

Apart altogether from his controversial theories, Dr Patten's volume has its uses We find there excellent figures and descriptions of many zoological facts, especially in regard to these ostracoderms As a text-book of the structure of *these animals and of the marine arachnids, i e*, limulus and its allies, Dr Patten's treatise is to be commended and may be accepted, as an exposition of an evolutionary view it cannot be ignored, but it must be studied with a more critical attitude

Guide to Midwifery By DAVID BERRY HART, M D Edin, F R C P Edin, Lecturer on Midwifery and Diseases of Women, School of the Royal Colleges Edinburgh London Rebman, Limited 1912 Demy 8vo Pp 790 Four illustrations in colour and 268 diagrams Price 25*s* net

Dr Berry Hart has written in this guide to midwifery a book of much originality in contents and arrangement. Part I gives a succinct account of midwifery from a modern standpoint To each chapter there have been *added, when necessary, instructions as to what practical* work should be done and what specimens examined in order that the student may know the thing itself as far as possible, and not its imperfect concept verbally expressed In Part II notes have been added to certain chapters elucidating difficult points and giving summaries of new operations and of views and theories which would distract the reader in a first study of the subject The result is a book of great interest and one which does credit to its author

In the chapter on the development of the ovary Dr Hart puts forward his views that the oocytes originate from an early division of the zygote, and that the primitive germ cells derived from this travel to the Wolffian ridge, where they pass into the germ epithelium Thus one primitive germ cell of the fertilised *ovum or zygote has formed the individual*, while the others have passed into its genital ridge on the Wolffian body Dr Hart, as he explains in the chapter on evolution in Part II, holds that there are two kinds of ova, which he terms the Wolffian and non-Wolffian oocytes He believes that there are also, in all probability, two kinds of spermatozoa, the Wolffian and non-Wolffian spermatozoon Two different kinds of spermatozoa have actually been described in man, but this observation is disputed He regards it as highly probable that when fertilisation takes place it is a Wolffian ovum which joins with a non Wolffian spermatozoon; and a Wolffian spermatozoon with a non Wolffian ovum In this way the sex is determined at the time of fertilisation The author's well known views on the origin of the uro genital organs are set out in the consideration of the development of the posterior end of the embryo

Just as these early chapters contain much that is of absorbing interest, so the reader will find all through the book evidence of the author's originality of mind and profound knowledge of the literature of the subject. In Part II the section dealing with evolution in its relation to obstetrics, that on the mechanism of labour, and the discussion of the mechanism of the third stage of labour—in which the author's own views are set forth very fully—all make interesting reading, as do the sections on the internal secreting glands in their relation to obstetrics, and the various theories of the nature of eclampsia

Dr Hart says in the preface that in his view it would be better if a treatise on midwifery were not illustrated at all, and if the student studied the text and examined physiological and pathological specimens, bones, and microscopic specimens, instead of merely reading the book and looking at the illustrations Recognising the fact, however, that this is not practicable, a number of illustrations are given; many of these are original, and the rest are taken from the best known atlases and monographs. The coloured plates are exceedingly good, and form a notable feature

We strongly recommend this book, not only to students, but also to their teachers

Occasional Papers on the Prevention of Some Common Diseases in Childhood By J SIM WALLACE D Sc, M D Glasg London Baillière, Tindall, and Cox 1912 Pp 103 Price 3*s* 6*d*

UNDER the above title Dr Sim Wallace publishes a series of papers which from time to time have appeared in various medical and dental journals The more important of these are essays on (1) Diet in Infancy and Childhood, (2) the Diet of School Children, and (3) the Prevention of Dental Caries It would be unfair to say that Dr Wallace has but one idea, but it cannot be denied that he lays more to the charge of "pappy food" than this undesirable form *of food deserves It is a physiological law that atrophy* or want of development follows want of use of any organ, and there can be no doubt that imperfectly developed and imperfectly mineralised teeth do result from the eating of soft foods, but there are other causes of dental caries and other causes of dyspepsias than defective teeth Dr Wallace's view that adenoids are almost confined to those children who sleep with open windows is perhaps, too eccentric to discuss seriously If we apply the physiological law that hypertrophy follows overaction, we arrive at the very sound position that the hyperplasia of the lymphoid tissue which constitutes the familiar adenoid vegetations must be dependent on over-work or over stimulation The chief function of the lymphatic system in childhood is bacteriolytic, so that on Dr Wallace's own method of argument we arrive at one of the causes of adenoids which can have no possible connexion with night air, and, indeed, one which is greatly aggravated by bad air It is far more likely that bronchitis and adenoid vegetations are caused, or at least promoted, by bad air, than that they are due to night air, as is maintained by Dr Wallace The development of the jaws and teeth by the mastication of hard varieties of food eaten is a result which needs no proof, though it is a truth that requires to be constantly brought home to those who have the charge of children, but that all the ills to which children are subject can be prevented by the author's dietary is a view which is not likely to gain general acceptance

---

A Text book of Practical Therapeutics By HOBART AMORY HARE, M D, B Sc, Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia Fourteenth edition London Henry Kimpton 1912 Pp 984 Price 21*s*

IN order to prepare for the present edition the book has been enlarged, thoroughly revised, and to a large extent rewritten When this work first appeared the treatment of disease was more empirical than it is to day Dr Hare's endeavour has been to link together the rather dry facts of materia medica with the results of laboratory investigation, so as not only to demonstrate the application of remedial measures to disease, but also to attempt to explain their employment upon a rational basis He has recognised the fact that the physician at the bedside needs and desires all the help he can get, whether it comes from laboratory experiment or from bedside experience, and furthermore wants this help in a form in which he can use it when face to face with problems which are of vital importance to him and to his patients. Accordingly, the work has been planned so that every aspect of therapeutics is considered, and also so that reference to any particular remedy or to the treatment for any disease is easy.

The work is divided into four parts. The first is headed "General Therapeutical Considerations," and numerous hints are given as to the mode of action of drugs, the modes of administering drugs, and prescription writing. Part II. contains a description of drugs themselves, including their physiological action, the conditions in which they may be employed, and the methods of their administration. This portion of the work has been brought thoroughly up to modern requirements; the uses of salvarsan, tuberculin, and vaccine therapy are duly described, as well as the recent ideas in regard to the employment of cardiac tonics, especially digitalis. An interesting account is given of the toxic action of digitalis which by its influence on the vagi interferes with the passage of the contraction wave over the bundle of His. Further, the digitalis stimulates the ventricle to increased activity, and this aids in the production of extra systoles. The development of this phenomenon or of dropped beats during the administration of the drug is regarded as an indication for stopping it. In Part III. remedial measures other than drugs are considered, and amongst them Bier's hyperæmic treatment is fully described. The fourth part of the work is devoted to the treatment of disease, the various maladies being placed in alphabetical order.

Taken as a whole, the book is a thoroughly good one, but it will be found more useful as a work of reference than for the use of students.

LIBRARY TABLE.

Précis Pratique d'Électricité Médicale. By G. GEIGER, Doctor of Medicine of the Faculté de Paris. Paris: Jules Rousset. 1913. Pp. 409. Price 6 francs.—This is a useful handbook of medical electricity. Speaking generally, its chief function is to explain those technical questions that are usually very troublesome to those who have not devoted special attention to the subject. The first part of this manual is confined to the study of those more or less elementary physical matters that it is essential to know thoroughly before it is possible to understand the procedure in medical applications. In this section are included points relating to the X rays, light, and heat, so far as they apply to medical work. In the second part the various forms of apparatus are described along with the principles upon which they work and the proper methods of using them. In the third part practical applications and the best method of dealing with any particular condition will be found. A system of selection has been employed, so that for any particular disease we are given only the method or methods that are known to be really useful. We are thus spared much that is of little or no benefit, and this is an example that might with advantage be followed much more generally than it is. The manual is fully illustrated by many diagrams and other figures, and the author has succeeded very well in carrying out the main purpose of this work.

Extraction of Teeth. By J. H. GIBBS. With 53 illustrations. Edinburgh: E. and S. Livingstone. 1912. Pp. 163. Price 7s 6d. net.—We are informed by the author in the preface that "no progress has ever been made by orthodoxy, and it is his deep conviction that the orthodox methods of extracting teeth are wrong in principle and bad in practice that has induced him to consent to give a wider publicity to his own heterodox views." What are these heterodox views? One is that only two pairs of forceps are necessary for the extraction of teeth, one pair for the removal of the maxillary teeth and another for the mandibular. Now, one factor that is necessary for carrying out tooth extraction in a really scientific way is that the blades of the forceps should accurately fit the roots of the tooth to be removed. If a series of molar teeth be taken, and the instruments suggested by the author and those usually advocated be applied to the teeth, there can be no question that with the latter a far more accurate hold can be obtained. The practical experience, too, of the large majority of skilled operators and teachers is in direct variance with the author's views, and we can only say that the method advocated is likely to lead to clumsy rather than to neat operations. The position advocated for the "prop" is in the front of the mouth, and the author's illustrations show the interference this must cause to the use of the fingers for gripping the alveolar process. A "prop" at the back of the mouth gives a clear and unimpeded view of the field of operation. There are other points in the book to which exception may be taken, notably the method advocated for grasping upper forceps. With his views on the employment of anæsthetics in dental practice we are in complete agreement, and there are several valuable hints of use to the practitioner. The book would be more readable if the author had not been so discursive in the treatment of several sections of his subject.

London County Council, London Statistics, 1911-12. Compiled under standing orders and regulations of the London County Council. London: P. S. King and Son. 1913. Pp. 651. Price 5s., post free 5s. 6d.—This volume, which we have received from the Clerk of the London County Council, contains most valuable and interesting information illustrated by maps and diagrams showing in diagrammatic form the statistics of the administrative county of London and of the public services carried on therein, together with certain statistics of the adjacent districts. To anyone interested in the life and welfare of London this book is invaluable.

JOURNALS AND MAGAZINES.

The Journal of Hygiene. Edited by G. H. F. NUTTALL, J. S. HALDANE, A. NEWSHOLME, C. J. MARTIN, J. C. G. LEDINGHAM, and G. S. GRAHAM-SMITH. Vol. XII., No. 4. December, 1912. Cambridge University Press. Price 7s. 6d. —J. A. Arkwright describes investigations on an epizootic disease which occurred amongst salmon and trout in the south-west of England during the summer of 1911. It presented the same symptoms as the disease which occurs in Germany, Austria, and France, known as furunculosis of salmon. Abscess-like cavities, softened hæmorrhagic foci, and small hæmorrhages in the muscles were of frequent occurrence, but were also frequently absent. Congestion of the lower intestine occurred constantly. A pigment-forming bacillus occurred constantly in large numbers in the blood and internal organs and in the muscular hæmorrhages, but was absent from the very large proportion of healthy control fish. This bacillus is probably identical with B. salmonicida and B. truttæ, and is almost certainly the cause of the epidemic disease. It was present in some apparently healthy fish bred in captivity. These may have been examined during the incubation stage, or may have been healthy carriers. The bacillus was destroyed in a few hours by sea-water, and even by a mixture of equal parts of sea-water and tap-water, though it lived for at least five days in tap-water. It is therefore improbable that the salmon usually became infected in the sea. Cultures of the bacillus soon die out at 36° C. Hot weather favours the development of the disease. As the author states, a number of points still require investigation: whether salmon coming up from the sea are infected before they enter rivers; whether the spread of the disease from river to river is only due to the introduction of fish from other rivers and breeding stations; whether other fish besides the salmonidæ are naturally infected, whether infection is more easily obtained by feeding or by pollution of the water with the bacillus, and, if the latter, whether wounds are necessary, the effect of the temperature of the water on the production and prevalence of the disease.—H. Chick, in a paper illustrated by several diagrams and tables, comes to the conclusion that the action *in vitro* of normal rabbit serum upon B. coli commune consists usually of three or more phases, the duration of which is inversely related to the temperature. The latent period which occurs on first mixing bacteria and serum is followed by a period of bacterial growth, which is followed by a period of bactericidal action. This may be final or may be succeeded by a second period of growth. The germicidal action takes place in accordance with a logarithmic law, so that death rate remains proportional to the concentration of surviving bacteria. The bactericidal action of serum thus falls into line with all other cases of disinfection hitherto investigated.—E. A. Cooper gives an account of some observations on the protective and curative properties of certain food stuffs against polyneuritis induced in birds by a diet of polished rice. His paper is divided into two parts. Part I deals with the quantitative determination of the preventive powers of various common foodstuffs against polyneuritis, and Part II with the fractionation of some of these food stuffs with a view to the isolation of the active constituent or constituents. Lean meat and fish were found to be of little value, but heart muscle and brain were greatly superior. Egg yolk considerably exceeds other foodstuffs in its capacity for preventing the disease. Dried brewers' yeast is possessed of considerable preventive power, nearly as great as that of egg-yolk. The antineuritic constituent of meat is not extracted by water, and only to a small extent by ether. It is readily extracted by alcohol, and after this procedure is easily dissolved in water. From egg yolk it can be easily extracted by both alcohol and ether. It is, therefore, not combined with fat or free lipoids, but is possibly present in the combined lipoids. Strychnine does not cure polyneuritis, but prolongs the lives of pigeons affected with the disease.—W. W. Clemesha criticises Dr. Houston's statement that "the original proportion between the various kinds of bacillus coli may be greatly altered," and that "the method aims at encouraging the typical bacillus coli to multiply and oust the non typical in the struggle for existence in a liquid nutrient medium." The writer has carried out a number of experiments with polluted water, fresh fæces, and mixed and pure laboratory cultures, and shows that there is practically no selective or "enrichment" action in favour of any species of coliform bacilli. He regards 18-20 hours as the best time for incubation in a fluid medium, and states that if this period be adhered to the results obtained give a reasonably accurate picture of the species of intestinal organisms present and their numerical relation to one another. He further discusses the possibility of assigning a definite place to certain varieties of fæcal organisms as a measure of their relative significance as indicators of dangerous pollution by a careful study of their life history.—E. H. Hunt contributes an interesting article on the regulation of the body temperature in extremes of dry heat founded on experience in the Deccan, India. He states that during extremes of dry heat no great discomfort is felt by healthy persons, and fairly hard physical work is possible in the sun, even with a "shade" temperature of 110° F. or more. The amount of water absolutely required, and actually consumed, is very large, and this is accounted for by the necessity for neutralising, in some circumstances, the whole heat metabolism (requiring up to 6000 c.c.), and in addition a variable but sometimes very large amount of heat added to the body by radiation and conduction. A healthy man carries in his body a large reserve of water, this reserve being mainly stored in muscle, and being so readily available that the percentage of water in the blood is not appreciably diminished, even when several litres of water have been lost by sweating. If, however, it be extensively drawn on, replacement seems to occupy many hours, and this delay is an important factor, forming a strong argument against any undue or needless use of stored water owing to a restriction of drinking.—G. Massee describes observations on discoloured spots sometimes present on chilled meats. Only one kind of fungus, Cladosporium herbarum, producing "black spots," is constantly present. The spots occur in the subcutaneous areolar tissue, first appearing as minute scattered points which gradually increase in size up to 1—rarely 2—cm. in diameter and retain a more or less circular outline. The circumference is seen to be fringed with dark coloured radiating hyphæ when examined under a low power lens. When small, the spots are grey, when large, dull black with a tinge of olive green. As a rule the spots are separated from each other by a distance of from 2 to 6 in., but in bad cases are present in groups. The fungus does not penetrate more than 4 mm. into the substratum. The black patches invariably remain dry—that is, there is never any indication of liquefaction or of putrescence set up by the fungus. It does not grow on bones or cartilage. It grows best at low temperatures. The characters and cultures of the fungus are fully described. It is evident that the meat is infected before it is packed. Certain other fungi occasionally forming spots on chilled meat are also mentioned, and the appearances of the infected meat and also of the fungus are shown in two coloured plates.—P. W. Bassett Smith contributes an article on certain points in the diagnosis and treatment of Mediterranean fever. In describing the agglutination method for diagnosis he shows that certain precautions ought to be observed (1) the culture should be proved to be active with known specific blood, and should not agglutinate with other sera, (2) both heated and unheated serum should be tested, (3) the test should be carried to high dilutions, 1/400th or more. In regard to treatment he draws attention to the extended employment of vaccines and yeasts or yeast products. Vaccines should be freshly prepared, and doses of 100 to 500 millions given at five to seven day intervals in the loin. With moderate hectic temperature this method may give excellent results, but is contraindicated when pyrexia is continuous or remittent. For neuritis he has employed yeast in 2 drm. doses, twice daily, apparently with beneficial results.—A. MacConkey describes his method of toxin production from the diphtheria bacillus, and in his first chart gives in the form of a curve the results obtained week by week from September, 1910, to July, 1912. From the point of view of weekly variations the curve only depicts what has been a universal experience, and one for which no explanation is forthcoming. It also shows that there are a rise and fall in the size of the minimum lethal dose during the summer and winter respectively, and the rise and fall are not gradual. At the end of the summer there is a marked increase in the production of toxin, and then the strength of the toxin remains high until about the end of March, when a drop occurs and the toxin production remains low until the autumn. Other charts illustrate the interesting fact that there is a similarity between the curve of toxin production and curves showing the incidence of diphtheria in the human subject. In another paper MacConkey gives the results of observations on the effect of heat (36° C.) on diphtheria toxin. He shows that when serum is kept in small bottles deterioration appears to take place on an average about six times as fast at 36° C. as in the ice chest.—H. Tebbutt describes experiments made in order to ascertain whether pathogenic organisms fed to larvæ can be recovered from the adult fly (M. domestica). He states that B. dysenteriæ (type Y.) cannot be recovered, unless flies have been bred from disinfected ova. B. typhosus was not recovered in a single case. Such organisms as "Bac. A." (Ledingham) could be recovered. He concludes that the possibility of flies becoming infected from the presence of pathogenic organisms in the breeding ground of the larvæ may be considered as very remote.—W. J. Penfold and D. Norris describe experiments on the generation time of bacteria. They conclude that the generation time of B. typhosus in 1 per cent. peptone at 37° C. is 40 minutes. Its rate of growth is greatly influenced by the concentration of peptone. Below 0·2 per cent. the generation time is inversely proportional to the concentration of peptone used. The addition of 0·175 per cent. of glucose to a medium containing only 0·1 per cent. of peptone lowers the generation time by about 50 per cent.

British Journal of Inebriety.—In the January number Dr. Herbert Rhodes writes on the Relation of Alcoholism to Tuberculosis. He prefaces his remarks by the statement that he includes under the term alcoholism all degrees of non-teetotalism, but his references throughout the article appear to be exclusively to cases of pronounced intemperance. The most interesting point brought out in the paper is the difference in this particular relation of alcoholism according to the social and economic conditions of the drinker, drinkers of the outdoor labouring class remaining relatively immune while their dependents suffer from the underfeeding and overcrowding and from the resultant tuberculosis. Dr. Rhodes has taken the views of a number of sanatorium physicians regarding the use of alcohol in phthisis, and candidly admits that he finds a general agreement that small doses are beneficial as a sedative or an appetiser at meals, though he is constrained to add that personally he regards such doses as "damnable in their moral and eventually in their physical effects."—A paper on Alcohol and Modern Life, by Mr. J. Lionel Tayler, being a portion of a popular lecture, gives a clear and, allowing for some slight teetotal exaggeration, a reasonable account of the physiological effects of alcohol and of the social causes and pathological results of excess.—In a brief article entitled, "When is a Man Drunk?" Mr. Norman Porritt has collected a number of remarkable legal, medical, and popular utterances showing the extraordinary confusion of opinion with regard to this question which has been very much before the public of late.—An illustrated article on the Church of England Temperance Society's Homes for Inebriates by the secretary of the society, the Rev. G. A. Thompson, completes the number.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

MEETING OF COMITIA.

A COMITIA was held on Jan. 30th, Sir THOMAS BARLOW, Bart., K.C.V.O., the President, being in the chair.

The following gentlemen having passed the required examination were admitted Members of the College: Anthony Feiling, M.B. Camb., L.R.C.P., Nathan Mutch, M.B. Camb., L.R.C.P., Robert Hunter Steen, M.D. Lond., and Francis Martin Rouse Walshe, M.D. Lond.

Licences to practise physic were granted to 98 gentlemen who had passed the necessary examinations.

Diplomas in Public Health were granted jointly with the Royal College of Surgeons of England to the following: Frederick John Ayre, Harold Balme, Jamasp Cursetji Bharucha (Lieutenant, I.M.S.), Elsie Mary Chubb (under the Medical Act, 1876), William Edmund Cooke, Archibald Ferguson, Clifford Allchin Gill (Captain, I.M.S.), Harvey Hilliard, John Edward Hodgson (Major, R.A.M.C.), Herbert Michael Henry Melhuish (Captain, I.M.S.), Alexander Loftus Otway (Captain, R.A.M.C.), and Percy Rose.

The following communications were received: 1. From the Secretary of the Royal College of Surgeons of England, dated Dec. 12th, 1912, and Jan. 10th, 1913, reporting proceedings of the Council of that College on Dec. 12th and Jan. 9th respectively. 2. From the Clerk to the Privy Council, dated Dec. 19th, 1912, enclosing a programme of the Fourth International Congress on Physio-therapeutics to be held at Berlin from March 26th to 30th next, and stating that should the College nominate a representative the Lord President of the Council would ask the Foreign Office to give him credentials as delegate of His Majesty's Government. Dr. A. E. Garrod was nominated as representative of the College. 3. From the Colonial Office, dated Jan. 3rd, 1913, with enclosures, concerning the appointment of some distinguished medical man to represent His Majesty's Government at the Tenth Session of the Australasian Medical Congress to be held at Auckland, Feb. 9th to 14th, 1914. The matter was left in the hands of the officers of the College. 4. From the Home Office, dated Dec. 20th, 1912, asking the opinion of the College on an application from the Liverpool Infirmary for Children for permission to use the prefix "Royal." A favourable reply was returned.

Sir E. Cooper Perry, Dr. F. W. Andrewes, Dr. E. H. Starling, and Sir J. Rose Bradford were elected councillors. Sir Francis H. Champneys [illegible] the College on the Central [illegible] April 1st next.

A discussion on the Insurance Act ensued.

Dr. J. F. POYNTON brought before the College certain difficulties in the position of Fellows of the College who are hospital physicians due to the altered conditions that have arisen with the establishment of the medical panels. He said that these difficulties related to the hospitals and their honorary physicians, to the doctors on the panels, and to the patients themselves. The main difficulty was the matter of [illegible] re suitable for hospital relief [illegible] doctor on the panel; there was some danger of patients being sent to and fro between the hospital and the doctor. It would often be onerous for the physician to out-patients to decide the question, and he was afraid the result would be that the hospital would be blamed for whatever happened. He hoped that the College would keep a sympathetic eye on the difficulties he had mentioned. He thought that the leading article in THE LANCET of Jan. 18th had explained the subject very clearly.

The PRESIDENT observed that the difficulties should be settled locally at the various hospitals. Two committees had already been appointed to consider the circumstances of the Insurance Act.

Sir DYCE DUCKWORTH (the treasurer) placed reliance on the [illegible] pitals, and referred to the plan [illegible] Hospital.

Some further discussion took place, but no resolution was proposed.

Dr. H. SAINSBURY brought forward the following proposition:—

> With reference to the medical working of the Insurance Act now in force, to draw attention to the resolutions passed at a meeting of the Joint Committee on Nov. 13th, 1912, and to urge upon the College the necessity for a further consideration of the present situation with a view to further action. [These resolutions were published in THE LANCET on Dec. 21st, 1912, p. 1742.]

Dr. Sainsbury urged (1) that the majority of doctors were working the Act under [illegible] under a strong sense of injury; [illegible] were temporary and could be adjusted; and (3) that in three months' time some further decision would have to be reached. He hoped that the resolution passed by the College would not remain as mere pious opinions, but that they would be acted upon. The general practitioners were the backbone of the profession, and they had never stood in greater need of guidance than at present. On grounds of freedom of action and development of character, and on the grounds of the interest of the insured, he urged that the College should give the matter its continued attention. He moved the following resolution:—

> [illegible] the Conjoint Committee at th[illegible] the resolution passed on N[illegible].

This was seconded by Dr. F. J. SMITH, who referred to the methods which had been adopted to force medical men to go on the panel, and trusted that the College would be roused to a sense of its responsibilities to the Licentiates.

The resolution was carried.

A report from the Committee of Management, dated Dec. 3rd, 1912, was received and adopted. The report was as follows:—

School, Fulham

laboratory instruc-

n to be added to the

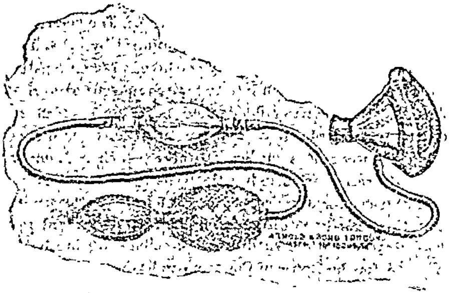
for their Diploma

After some further formal business the PRESIDENT dissolved the Comitia.

New Inventions.

A NEW CHLOROFORM APPARATUS.

I HAVE been using a modification of Junker's method of giving chloroform with the most satisfactory results. As there are no valves to obstruct respiration, no taps to fumble with (often in the middle of the night), no lint or flannel to become damp and impervious, as the strength of the vapour can be regulated and easily measured, and as there is, in addition, a free access of air, almost every possibility of danger is done away with. This apparatus consists of a glass bulb about the size of a duck's egg. There is a tube at either end to connect it with a face-piece on the one hand and a rubber bellows on the other. The exit tube is prolonged into the middle of the bulb and ends in a pinhole aperture. The inlet tube is very similar, so much so that the bulb is in every respect reversible. Two or three drachms of chloroform can be put in at either end and the connexions can be made at either side without the least fear of the liquid escaping to burn the patient's face or to go down the patient's throat, which has caused many accidents with the ordinary Junker. It can be easily demonstrated that each pint of air blown through this bulb carries with it 2 minims of chloroform, no matter what position the bulb is in. In fact, it is like a chronometer which has to keep good time no matter how the ship rolls. There is no necessity whatever to catch the inspirations.



The size of the pinhole in the middle of the bulb is so fixed that a constant flow of vapour can be kept up with a definite strength by a free use of the bellows, and one can leave off blowing for from 10 to 15 seconds without the current ceasing. This

and reduces the use of

I most urgently recon

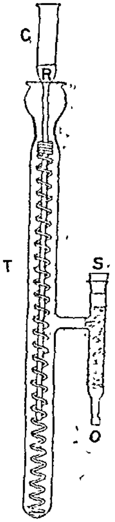
last a life-time. It should have an aperture without valves or obstructions that will allow free respiration and the advent of additional air. For midwifery this method is simple and constant by comparison with the so-called open method, where the vapour is erratic and the materials used may soon become damp and impervious by the expired moisture. It is the primitive methods that have been used in the administration of chloroform that have brought most undeservedly the best of all anæsthetics into disrepute Medical men who propose to use this method should ascertain how much chloroform is abstracted from it by the passage of a measured quantity of air. The illustration will explain the simplicity of this method. A piece of dry Turkey sponge, 1 × 1 × ½ in. in the bulb, absorbs the condensed moisture. With it the vapour is continuously constant at 2 minims of chloroform in each pint of air driven through.

The apparatus is made by Messrs. Arnold and Son, of Giltspur-street, London, E.C.

Harlesden, N.W. ALFRED G. JONES, L.M.S.S.A.

SIMPLE APPARATUS FOR INSERTING RADIUM INTO LENGTHS OF STERILE RUBBER TUBING.

IT is clearly desirable that in hospitals and other institutions using radio-active substances the operator should be protected as far as possible from the deleterious effects of the radiations. This especially applies where it is required to insert a tube of radium, enclosed in its cylindrical metallic filter, into a long length of rubber tubing, preparatory to treating an internal growth. Lengths of tubing, closed at one end and only ·5 mm. thickness in the wall, are specially made for such a purpose, and the usual practice consists in gradually working the radium along the tube with the fingers, probably assisted by a trace of lycopodium powder or French chalk. This is a very tedious process, involving a dangerous exposure to the radiations, and in addition necessitating final sterilisation by fluids or vapours. The following method has therefore been devised in the Physics Laboratory for use in the radio-therapeutic department of the Cancer Hospital with a view to overcoming these objections. The requisite apparatus consists of a glass tube T (see figure) which may be of any convenient length and about five-eighths of an inch in diameter. Its upper end is enlarged to form a cup as shown, and so graduated in width at the neck that the rubber tube R, when slipped over the tapered end of the short glass tube C, shall form an air-tight joint when C is lowered into T (it is shown raised in the diagram). Within the long tube T there stands a nickel wire spiral, the diameter of each turn of which slightly exceeds that of the cylindrical radium filter. The tapered end of C must also be large enough at the opening to allow the filter to pass freely through it. A side tube is also provided. It is plugged at the top by a rubber stopper S, the inside being packed with cotton wool and the lower part drawn out to take a rubber connexion. To prepare the apparatus, the short tube C is removed together with the rubber tubing attached to it, so that the latter may be coiled into a Petri dish and sterilised at 120° C. The tube T must then be plugged with cotton wool, the stopper S removed, and the whole sterilised by hot air at 160° C. When required for use, T is held vertically in a clip stand, the cotton wool plug is removed, and a flame passed once or twice over the mouth of the cup. The rubber tubing is then lifted from the Petri dish and guided by means of sterilised forceps into the upper end of the spiral. When the rubber tubing has been run in, the stopper S is replaced, and O connected to a vacuum pump. A slight exhaustion suffices to expand the rubber tubing till it fills the spiral, so that if the radium in its filter be picked up with forceps and dropped into the tube C it falls at once to the bottom. On allowing air to re-enter T through the cotton wool in the side tube the rubber contracts to its original dimensions and closely fits over the radium filter.



The loaded tubing may now be easily lifted out and the radium applied directly as required. The method is in reality simple and rapid. It has the advantage that the fingers are never in close proximity to the radium, it enables narrower rubber tubing to be used than heretofore, and since the sterilisation is done by dry heat, the use of irritating substances is entirely avoided. The radium may of course be quickly removed from the rubber tubing by replacing it in the tube T, which is then again exhausted as before and inverted.

C. E. S. PHILLIPS, F.R.S.E.

Cancer Hospital, S.W.

may mention those directly influencing the gland itself, so that it is less able to counteract the toxic agent without undergoing hypertrophy; such as puberty, pregnancy, defective hygienic conditions, infective disease, and emotional states. It appears also to be definitely established that an organically impure water favours the development of the disease, and that water containing lime may possibly exert an influence in this direction.

In his endeavours to discover the actual exciting cause of goitre Major McCarrison has paid special attention to water and soil. He refers in some detail to instances on record of waters in various widely distant parts of the world accredited with goitre-producing properties, and then proceeds to record his own observations, which have demonstrated that the residue separated by filtration from the water-supply of Kashrote, one of the most goitre-ridden villages in his district, is capable of producing goitre in man under experimentally controlled conditions usually on about the fifteenth day. Répin and Bircher have recently succeeded independently in producing goitre in rats by giving them water from notoriously goitrous districts. The influence of soil and geological formation has been studied at considerable length, and it is found that although goitre is most commonly associated with limestone and dolomite formations and with marine deposits generally, it can and does occur on almost every other geological formation. It is also shown by Major McCarrison that chemical substances in water, such as lime and magnesium, are not the causal agencies, since goitre is known to occur in districts where rain-water only is drunk. From a consideration of the results of his own experiments with the Kashrote water, including the production of goitre in himself as one of them, Major McCarrison concludes that thyroid enlargement can be experimentally produced in man within a few weeks by the administration of the suspended matter separated by filtration from goitre-producing waters, but that boiling this residue deprives it of this property, and that filtration through a Berkefeld filter probably does the same, since with water so treated he did not succeed in producing goitre within the limits of the 55 days it was employed. It is on the basis of these facts and of a review of the data concerning the etiology of the disease to which we have briefly referred that Major McCarrison rests his contention that the cause of goitre is the presence in suspension in water of a living agent, a view which is supported by the experiments of Bircher on rats carried out subsequently to his own observations. But the soil as well as the water-supply may be a vehicle of contagion of this living excitant, and possibly a direct infection by contact may occur.

Attempts to isolate the supposed living agent have so far failed, but it is shown that goitre-producing waters are pre-eminently those in which micro-organisms can thrive. Although blood changes of a fairly definite character are to be found in goitre, Major McCarrison has to admit that neither he nor other observers have been able to obtain micro-organisms from the thyroid except in acute inflammatory conditions. He brings forward evidence suggesting that the intestinal tract is the seat of infection. The evidence consists in the main of the beneficial effects of intestinal antiseptics, such as salol and thymol, in the treatment of goitre, and the good results obtained with vaccines prepared from organisms which normally occur in the bowel, and from the mixed organisms cultivated on Musgrave's medium from the fæces of goitrous individuals. Major McCarrison has followed up this suggestion by attempting to transmit goitre to animals, notably goats, by infecting their water-supply through the medium of patients suffering from goitre, and has obtained enlargements of the thyroid glands in as many as 50 per cent. of them. The chain of evidence brought forward with such skill by Major McCarrison, though highly suggestive, must be regarded as incomplete until the living causal agent is actually isolated and its pathogenicity established. Meanwhile he is to be congratulated upon the use he has made of his opportunities and upon the success which has apparently attended measures of prevention and treatment based upon his hypothesis as to the causation of the disease. It is to be hoped that he will continue his researches and that other observers will follow up the suggestive lines of research which he has opened out.

Vaccination and the Medical Education of the People.

At the annual dinner of the Association of Public Vaccinators of England and Wales, of which a short note appears in another column, three speakers—viz., the President of the Association (Mr. Arthur Maude), Sir James Crichton-Browne, and Surgeon-General G. J. H. Evatt—in weighty and well-considered words, and approaching the subject along different routes, insisted upon the vast importance of the education of the people in medical truths. It was natural, seeing the occasion of the dinner, that the common text of all speakers should be the dangerous laxity of existing vaccination legislation. The attitude which, with the noble object of giving a greater measure of freedom and initiative to the people, has dictated our recent legislation with regard to vaccination was declared to be reckless in the extreme. But those who have not studied the subject carefully, who are not prepared to sift and deal with the masses of relevant statistics, and who are not fortified by acquaintance with the latest scientific teachings, can hardly be expected to share this disquieting belief. For we are secured to a great extent from epidemic attacks of small-pox by the most efficient public health service in the world, and this security is assisted by a level of domestic decency and of material comfort which, however deplorable the lapses from this level may be in too many localities, is yet far higher than the standard prevalent in most other countries—countries where a sparser population and a less complicated system of commercial enterprise exist. Relying thus on our vast and elaborate system for the maintenance of the public health, we are allowing to accumulate amongst us masses of explosive material from which trails are laid throughout the whole of the country, and of these only one may require a light to cause a disastrous and general conflagration. As long as the outbreaks are small, and as long as the early cases can be swiftly detected, so long can the spread of infection be limited with some approach to certainty, notification and segregation being sufficient for the purpose. So effective are these two measures, taken in conjunction with our fairly satisfactory sanitary conditions at large, that already many beds originally allocated for the treatment of small-pox have been devoted to other purposes by various authorities, and no one can say that this policy is other than economical. But if some of these small explosions, occurring in the centre of a highly inflammable population, should refuse to be stamped out, and the flame should burst through our protective cordons and rush into the general territory beyond, no one can say where the mischief may end.

Here—that is, in the magnitude of the disaster that we may be courting—lies the danger of actively opposing vaccination, and lies also the reproach of those who have too lightly yielded to the fears of unpopularity, or have allowed themselves to remain in ignorance of the facts. The wisdom of systematic vaccination and revaccination depends upon a series of facts which are not comprehended by the people, but which should receive the attention of their leaders and representatives. Many prefer to submitting to vaccination the freedom, as they consider it, of remaining in an inflammable condition. They enjoy a system of protection which is admirable so long as no great danger arises, and they prefer this modified safety to the basic security of making themselves uninflammable. We agree with the protagonists of the Association of Public Vaccinators that the public is not properly informed, and that it has selected its course accordingly. The position requires to be temperately but anxiously placed before the people in a systematic manner; a course of education in vaccination should be attempted, similar to the courses upon eugenics, rearing of infants, and domestic hygiene, which are from time to time announced in our columns. Primarily, that education must come from the medical profession, but secondly, the coöperation of the public is required for the enlightenment of the public. Those members of the public whose advantages in education, and whose development of reasoning power allow them to perceive the danger of the present condition of affairs should be asked to awaken the communities in which they live to this danger. Such assistance from laymen would remove from the educational campaign any suspicion that its teachings emanated only from the medical profession and represented merely an attempt on the part of that profession to maintain a belief founded rather upon tradition than upon circumstances as they are.

The members of the Association of Public Vaccinators, acting here for all medical practitioners and not in any selfish or official spirit, have been, and are, doing their best to disseminate the facts about vaccination. They make known to the best of their ability the position of modern vaccination, showing that while its practice can be supported by masses of unassailable figures, its theory, now that the value of Dr. S. MONCKTON COPEMAN'S labours has been appreciated, is equally unassailable from a scientific point of view. But the Association of Public Vaccinators is not a large or wealthy body, and nothing like a system of popular education can be carried on through its endeavours alone, however devoted. In Germany the work of instruction is done largely by the State, and the German mind finds it completely ridiculous that we in this country—the country where Eastern wisdom in regard to the treatment of small-pox was first turned by Western minds into a practical direction—should be content to leave our inhabitants so ignorant of the facts about vaccination and so free to do as they please that a vast proportion of our population is now not really protected from small-pox.

"Ne quid nimis."

CONDUCT AND CHARACTER.

THE Birmingham Studies in Social Economics [1] are the outcome of the inquiries of students working for the social study higher diploma or for the higher degrees of that University. The University directs a course of preparation for public and social service which combines systematic instruction with practical training under supervision in the city. The first of these studies is an essay which is considered by Dr. J. Rendel Harris to be more than an academic dissertation; a real contribution to a very pressing problem—that of raising the children of the drunken and dissolute from the place of their degradation to higher planes of social life and worthiness, where it is expected they will when old enough be able to maintain themselves unaided. Miss Thomson attempts to apply the test of statistical experiment to the problem and to find out for us whether environment is able to unsay what heredity has been proclaiming *ore rotundo*. She has studied the records of a few industrial schools and orphanages, and has taken as her standard of efficiency Mr. Charles Booth's classification ("Labour and Life of the People"). This classification passes from Class A, which consists of "some occasional labourers, street sellers, loafers, criminals, and semi-criminals," through C and D, below and upon the poverty line, up to H, "the servant-keeping class." Her chief purpose is to show the overwhelming part played by environment in the building up of human efficiency, and her statistics show that 72 per cent. of rescued children have justified the expectations formed for them, and of the remainder 13 per cent. failed for reasons of mental rather than moral deficiency. It is very encouraging to see such statistics, which, owing to the care expended on the examination of them, may be taken as representing the actual facts. They justify the very general opinion that of all forms of charity that which is directed to the rescue of waifs and strays is fraught with the most fruitful benefit. They also justify our industrial school system when these schools are conducted by kindly and competent people. The author is, however, anxious to claim more for them than merely this, and we would be over ready to allow her claims if we could do so in the purely scientific atmosphere in which our labours are conducted. Just as insanity may be really "disorder of the mind," but, so far as it practically concerns the social body, is undoubtedly "disorder of conduct," so, as Professor F. W. Mott has recently pointed out in his studies of pedigrees, may prudent conduct mask the sense of colour—vermilion and gold running riot throughout it—if we remember our early readings, much concerned with the human voice, yet the old Celtic heroes were as given to the wine-cup as Odin himself. Wine and song, in popular philosophy, have always been twin brothers, despite the silence of Teutonic and Cymric classics. Wine implies excitement, and the true originality of the latest suggestion concerning the singing of birds lies in this that song depends on a lubricant rather than on an intoxicant.

[1] Environment and Efficiency. By Mary Horner Thomson. With a Preface by J. Rendel Harris, LL.D. (Birmingham Studies in Social Economics, &c.). London: Longmans, Green, and Co. 1912. Pp. 102. Price 2s. net.

INJURY AND PULMONARY TUBERCULOSIS.

A CONNEXION between pulmonary tuberculosis and injury has been asserted by some writers. Mendelssohn has recorded 9 cases and collected 17 others in which injuries to the chest of various kinds were followed by pulmonary tuberculosis. In some hæmoptysis occurred at the time of the injury or soon afterwards; in others cough and pleurisy ensued within a few days or weeks. Mendelssohn's theory is that in such cases the lung is lacerated or contused and becomes infiltrated with blood or inflammatory products. These favour the growth of tubercle bacilli, which he assumes to be more or less ubiquitous. On the other hand, Dr. Percy Kidd believes, in consequence of the rapidity with which pulmonary symptoms appear, that the injury rouses into activity some latent tuberculous focus, possibly by lacerating its capsule. In the *Boston Medical and Surgical Journal* of Jan. 16th Dr. J. W. Hawes, secretary of the Board of Trustees, Massachusetts Hospitals for Consumptives, and Mr. A. Drinkwater, an attorney and a member of the Board, have brought forward some new evidence, and discussed the question from the legal aspect. The legislation of recent years which makes employers liable for the consequences of accidents to their employees gives an additional interest to the question. They first discuss some cases reported by Dr. C. C. MacCorison, superintendent of the North Reading Sanatorium. In 6 cases out of 175 he found that the patients connected their disease with an injury. In one a man was examined at the Massachusetts General Hospital in June, 1910, as a matter of routine, and told that his lungs were perfectly sound. He was in good health and so continued until Feb. 12th, 1911, when he was hit on the chest in a fight and fell unconscious from the blow. A week later the cervical glands swelled rapidly, and in March tuberculosis was found in the lungs. In the other 5 cases there was a considerable interval between the injury and the development of the disease, and therefore the evidence of a connexion is unconvincing. The following case, reported by Dr. Hawes, appears to be a striking example of such a connexion. In October, 1908, while on duty on a motor-cycle, a policeman in excellent health sustained an accident and hurt his right side severely. Immediately he suffered from hæmoptysis, which continued until the next day. For a long time after the accident he had pain in the right side, and he never felt as well as before. He suffered from slight cough and occasional hæmoptysis, and constantly lost weight and strength. However, he continued on duty until March, 1909. From this time until August he was treated by a practitioner who told him that he was not suffering from tuberculosis. However, in August he was examined by three specialists, who found tuberculosis of the right lung. After that the disease rapidly developed. Dr. Hawes was asked to investigate the question whether he should receive a pension based on the fact that his condition was due to the accident while on duty. In view of the fact that medical examination had shown that he was in perfect health previously and was exceptionally strong, Dr. Hawes reported that the disease was directly due to the accident. There is another class of case in which the injury is not to the chest, but to another part of the body. Here the question of a connexion is far more difficult. The following is an example. A married woman, aged 22 years, had been examined many times during minor illnesses by her family doctor and found to have perfectly sound lungs. In September, 1909, while leaving a tramcar, her hand was slammed in the sliding door and severely crushed. She was taken to hospital, where it was found that a miscarriage had taken place. After treatment she returned home. She continued to lose blood off and on for two months and did not regain her usual health. In January, 1910, she developed a cough, and in March was found to be suffering from pulmonary tuberculosis. In an action for damages Dr. Hawes gave evidence to the effect that the tuberculosis was directly connected with the accident. The jury awarded damages, and the Supreme Court upheld this verdict. Recently the Supreme Court of Minnesota gave damages for the injured persons following circumstances. A robust man, aged 43 years, in perfect health, according to good medical evidence, received a severe injury to the head. There was considerable shock and concussion for which he was confined to hospital for a month. He steadily lost health and strength, and soon developed consumption, from which he died eight months later. For the defence it was argued that men of robust health are often attacked by consumption. The Court, however, decided that the evidence was sufficient to sustain a finding that the injuries sustained were the proximate cause of death.

THE TREATMENT OF DISSEMINATED SCLEROSIS WITH INJECTIONS OF FIBROLYSIN.

DISSEMINATED sclerosis, one of the very commonest diseases of the central nervous system, is at present enshrouded in obscurity as far as its exact etiology is concerned, and the chapter of its rational therapeutics, therefore, still remains to be written. As a consequence, innumerable medicaments have been and are being tried in this affection, but the specific, if there is one, has not yet been discovered. During the last five years Dr. Nonne, of Hamburg, has used injections of fibrolysin in a large number of cases with satisfactory results, but his endeavours do not appear to have aroused much interest either by way of criticism or corroboration. One of his assistants, Dr. Max Fraenkel, has published in the *Neurologisches Centralblatt* for January some account of his experiences with this drug in 75 cases of disseminated sclerosis, taken partly from Dr. Nonne's private and partly from his hospital practice. Merck's ampulles each contain 2·3 c.c. of fibrolysin, which is a combination of thiosinamine and sodium salicylate; this amount was injected into the gluteal region every three or four days for six weeks at a time. Of the 75 cases, 54 were hospital patients and 21 private. Of the former, 19, and of the latter 14, were uninfluenced by the treatment; 15 showed a certain amount of improvement, estimated by actual improvement in the physical and objective signs of the affection, and not merely by the patients declaring themselves better and stronger. In no less than 27, however, the results obtained were apparently very satisfactory, inasmuch as various objective symptoms and signs entirely disappeared. In several cases a return of certain symptoms was met by resorting to the treatment again, with notable improvement almost immediately. Dr. Fraenkel says that the injections can be carried out over a much longer period than six weeks without difficulty or danger. Whether there is a relation of cause and effect between the injections of fibrolysin and the subsequent improvement is, of course, not to be lightly decided, for it is notorious that many cases of the disease show remarkable remissions, while in others very long intervals elapse between the appearance of the various symptoms Further, the effect of fibrolysin on other morbid conditions (cicatrices, contractures, fibrosis, and strictures) is not clear, and even assuming the reality of its action on fibrous tissue we do not know that it possesses a similar action on glial tissue

GASTRIC SYMPTOMS DUE TO COLONIC STASIS

THE doctrine that serious symptoms may follow chronic stasis of the contents of the colon is well known in this country, mainly through the stalwart advocacy of Mr W Arbuthnot Lane while it is held widely in America An interesting case is reported in the letter from our Paris correspondent in which severe gastric symptoms were present and were thought to be due to a gastric ulcer, for there was vomiting and pain supervened two or three hours after a meal An X ray examination showed that a bismuth meal stayed for two or three days in the cæcum To remedy this condition an ileosigmoidostomy was done but the symptoms were not relieved A subsequent colectomy, however, was followed by rapid recovery Few will be found to dispute that in some cases there is a very definite connexion between gastric symptoms and colonic stasis and the case recorded from Paris proves that the removal of the colonic stasis may be followed by restoration to health Opinions, of course, differ widely as to the proportion of cases in which it is necessary to perform an ileosigmoidostomy or to resect a portion of the large intestine for obstinate constipation It seems at present wiser to keep to the *via media* but such earnest attention is now being paid to the subject that in time we shall be able to recognise with far greater certainty in what cases operative interference is desirable

THE BACTERIOLOGY OF PERITONITIS

IN the *American Journal of the Medical Sciences* for October, 1912 Dr Morris Fishbein has published an important paper on the bacteriology of peritonitis based on bacteriological examination of material obtained from the peritoneal cavity after death in cases of peritonitis at the Rush Medical College Chicago, and on previous work on the subject by two American writers—Flexner and Minihan Dr Fishbein follows the classification of Flexner, who divides all cases of peritonitis into primary, exogenous and endogenous Primary peritonitis is due to previous chronic diseases or to an infectious focus in some other part of the body, from which the infecting organism is brought by the blood or lymph channels to the peritoneum Exogenous peritonitis is due to infection from wounds of the peritoneum, including laparotomy, or to septic abortion Endogenous peritonitis is due to organisms coming from foci in relation to the peritoneal cavity, of which the most common is appendicitis The nature of the inflammation—whether serous fibrinous, purulent, or of other type—does not bear any relation to the nature of the primary lesion when such exists nor does it seem to be influenced by the kind of bacteria present, whether alone or in combinations of various kinds Adding together his own cases and those of the two previous writers Dr Fishbein has analysed 342 cases The organism most frequently found was the colon bacillus which was present in 183 cases and in 54 of these in pure culture, but in the majority of cases in combination with other organisms, such as staphylococci and streptococci The other organisms were found in the following order of frequency streptococcus, 143 cases, staphylococcus, 83; pneumococcus, 37, bacillus mucosus, 15, gas bacillus, 11, typhoid bacillus, 9, bacillus proteus, 9, bacillus pyocyaneus, 8, bacillus cloacæ, 3; micrococcus tetragenes, 2, bacillus lactis aerogenes, 1, bacillus paratyphosus, 1 In none of the cases was the gonococcus found The pneumococcus seemed to be particularly associated with primary peritonitis The typhoid bacillus was found both in cases in which there was perforation of the intestine and in which there was not The cases in which there was no perforation may have been examples of primary peritonitis The majority of cases of peritonitis were endogenous and due to a combination of the colon bacillus and other organisms, usually staphylococci and streptococci With perfecting of aseptic operative technique exogenous peritonitis is becoming less common In 25 per cent of Dr Fishbein's cases the peritonitis was primary In practically all the resistance of the patient was lowered by some chronic condition such as atrophic cirrhosis of the liver, chronic endocarditis and tonsillitis, marasmus or diabetes In such condition the peritoneum fails to combat organisms brought to it by the blood stream In other conditions, as when a suppurative focus exists in some other part of the body, as in acutely infected tonsils or an infected puerperal uterus highly virulent organisms are poured into the blood and a terminal acute infection of the peritoneum occurs To such causes the " idiopathic " peritonitis of the older writers is to be referred

TEACHING, LEARNING, AND LIFE[1]

Edward Thring the great headmaster of Uppingham School, has now been dead a quarter of a century, but the spirit of his teaching still survives, not only in the memories of those who came into actual contact with him, but in much of the work constructional and theoretical, dealing with the education of this country He was an extraordinarily simple single minded man determined to refound his old grammar school on the lines which he thought right and to carry it on along those lines through good or ill report He had sore troubles and not a few opponents, as every such enthusiast must have He trampled on what he thought were idle prejudices he did not mince words; occasionally he administered a justice whose roughness was more apparent than its purity but the nobility of his motives the courage of his actions and his readiness to sacrifice all for his ideals were alike so obvious that he won support and admiration and following in the places where, if only where, he valued it To medical men there is one episode in his career that should always appeal When a severe epidemic of typhoid fever fell upon the school in its little Rutlandshire home, Thring acting with the directness with which nowadays a military force would be ordered to evacuate an infected camp mobilised his great school, the inhabitants of 12 boarding houses with a concourse of dependants, masters servants, and attendants, and placed them within three weeks in a Welsh fishing village And a few hours after the reassembly of the school, with the coöperation of a brave and sorely harried staff, he had invented a system of discipline so exactly suited to the new conditions while founded on the old, that work and games alike went on with unbroken serenity. Thring's strenuous life of work and thought left little time for leisurely literary production, but he wrote two small books on education, setting out his reasons for his theories and practice, and published a volume of addresses and another of sermons Many of his letters were published in an interesting but sorely belated biography, while he left behind him an unpublished manuscript entitled "Education and Idolatry" From this material H and M P, with the sanction of the surviving family, have selected certain passages illustrative of the nature of Thring's counsels The work has been judiciously and piously done, while many of the pregnant sentences quoted should inspire the reader to consult the originals from which they have been taken. Says Thring, for example: "I do not mind whether things go entirely right or not. Nothing goes entirely right. Any fool can find fault. And road-makers cannot be so clean as those who walk on the roads they have made." Was ever the position of the mere critic compared in a happier way with that of the inventor, with, be it noticed, no undue laudation of the latter? This little book is full of similar aphorisms.

THE GERMICIDAL PROPERTIES OF TOBACCO SMOKE.

IT is not surprising to learn that tobacco smoke is inimical to the activity of micro-organisms, since it contains, amongst many other things, pyridin, which has been shown to be a powerful germicide. Definite experiments have recently been made which show that tobacco smoke rapidly destroys in particular the comma bacillus of cholera. *A good many years ago it was reported by the senior* medical officer of Greenwich workhouse that the tobacco-smoking inmates enjoyed comparative immunity from epidemics, and tobacco-smoking was believed to have had a disinfectant action in cases of cholera and other infectious diseases. Again, during a cholera epidemic at Hamburg it was reported that not a single workman engaged in the cigar factory in that city was attacked by the disease. Later it was stated that amongst a body of 5000 cigarmakers only 8 cases and 4 deaths from cholera occurred. Subsequent experiments proved that tobacco smoke destroyed the bacilli of Asiatic cholera as well as pneumonia, and there was some evidence also that tobacco smoke was preventive of some forms of nasal catarrh. It is interesting to note that pyridin is official in the French pharmacopœia, and in France it has been employed in the form of inhalation in asthma, emphysema, and angina pectoris, and mixed with peppermint in diphtheria. Excessive tobacco-smoking, of course, may easily give rise to constitutional effects which diminish the resisting power of the body to disease, in which case it is probable the habit would afford not only no protection but an opening for invasion.

ADRENAL HYPERNEPHROMA IN A YOUNG GIRL, WITH PRECOCIOUS DEVELOPMENT OF SEXUAL CHARACTERISTICS.

IN the recently issued annual volume of *Guy's Hospital Reports* is a brief paper by Dr. Herbert French on a rare condition, of which up to the present less than 20 cases have been recorded, where a tumour of the suprarenal cortex has been associated with abnormal development of the external genitalia and the characteristics of sex. Dr. French's patient was a little girl of 6½ years, who was admitted to Guy's Hospital on August 18th, 1910. She had always been a very healthy child, except that since she was 12 months old she had been subject to periodic attacks of vomiting several times a year, attacks which were gradually becoming more intense. In this little girl pubic hair began to develop when she was eight months old, and it increased in amount steadily for some years. There was none in the axillæ or on the face. For six months before admission she complained of pain in the left side of the body. She was found to be a healthy looking child, bright and intelligent, not unduly fat, with undeveloped breasts, but with a remarkable development of pubic hair and with an equally remarkable hypertrophy of the clitoris, which projected between the labia and separated them to a notable extent. A relatively large tumour was felt with ease in the left side of the abdomen, moving up and down with respiration, smooth and free from nodules, but very tender on the slightest pressure. It extended almost to the mid-line, above the umbilicus, and reached from the left hypochondrium into the left flank. There were definite indications that the tumour growth was compressing the lower lobe of the left lung. On Sept. 1st the little patient was operated on, and the mass was found to be a suprarenal tumour which almost completely surrounded the left kidney, making it impossible to remove one without the other. The suprarenal tumour was of a curious yellow ochre colour, very vascular and very soft. Although it was creeping down all over the capsule of the kidney, it did not invade the latter in any way. The kidney itself looked perfectly normal. The child died a few days later, when numerous secondary deposits, all yellow ochre in colour and varying in size from small dots to growths half an inch in diameter, were found scattered through the lungs. The uterus and ovaries were perfectly normal. Sections of the growth showed columns of large polyhedral cells, mostly arranged in a perivascular fashion. It may be described as a perithelioma of mesoblastic origin rather than a carcinoma.

KERATODERMIA BLENNORRHAGICA.

Dr. H. Swift, of Adelaide, has given an account of a cas of gonorrhœal keratodermia, the first recorded in Australi as far as he is aware, in the *Australasian Medical Gazett* of Nov. 30th, 1912. It is an extremely rare condition. Th first example recorded in England was a patient of D J. H. Sequeira, brought before the Royal Society Medicine in March of last year. Dr. Swift's patient was man, aged 35, who was admitted to hospital sufferi from gonorrhœa with polyarthritis for the second time i six years. On the dorsu of each foot were a few discre pustulous spots one-third to three-quarters of an in in diameter; in the most recent the outer margin the area of cuticle involved was raised very slightly a thin layer of cloudy serum. The centre was yellow, conve and raised, being in the process of becoming hardene Later, the cuticular rim became broken, the centre bein raised into a clear horn-like projection. Later still th centre became opaque, having an appearance not unlike tha of a rupial crust. In their subsequent course these pustul areas displayed the tendency to incrustation in a ve marked degree, and they also increased in size centr fugally. Fresh pustules produced on the shins and els where by extrinsic causes took on similar keratot characters. Attempts at discovering the gonococcus i the discharge from these cutaneous lesions proved abortive and treatment by injection of stock gonococcus vaccine was quite futile. The patient's urethritis was, howeve very persistent, and the condition conforms in all essential to that described by other dermatologists as occurring i connexion with severe and generalised gonococcal infec tions. Treatment is usually unsatisfactory, though in on case, that recorded by Dr. Sequeira, the use of gonococca vaccines proved highly effective in inducing a cure. Dr Swift remarks on one curious point, the offensive smell o the patient's skin. This was so extreme that the man ha to be isolated, and local applications of formaldehyde wer necessary in order to mitigate the odour.

A DISCUSSION on Ventrifixation of the Uterus has bee arranged to take place on Thursday, March 6th, in th Obstetrical and Gynæcological Section of the Royal Societ of Medicine. The subject will be divided into three parts (1) Indications for the Operation, to be opened by Dr. W. S. A. Griffith; (2) Varying Technique of the Operation to be opened by Professor Henry Briggs (Liverpool); and (3) Clinical Results of the Operation, to be opened by Dr.

A E Giles Anyone desiring to take part in the discussion should forward his or her name to one of the honorary secretaries, Dr Walter Tate, 32, Queen Anne street, W, or Dr T Watts Eden, 26, Queen Anne street, W, not later than Saturday, March 1st

STILLBIRTHS IN RELATION TO INFANTILE MORTALITY

The Report of the Special Committee of the Royal Statistical Society on Infant Mortality

IN a recent number of THE LANCET[1] the appearance was announced of a remarkable report on infantile mortality, prepared by a special committee of the Royal Statistical Society

For the first time in our experience the subject of mortality in early life is there discussed with reference to every important country in Europe and America That the problem had never previously been treated with equal success, even in our own country, should imply no censure on modern medicine, for it is only very recently that means have been available for estimating the influence of stillbirths on mortality in early childhood, for which purpose facilities are now afforded under the Notification of Births Act Again, the gradual and conspicuous advancement in every branch of sanitary knowledge must assuredly contribute to the greater accuracy of statistical returns The special committee entrusted with the preparation of this report consisted of Sir William Dunbar, Sir Shirley Murphy, Dr R Dudfield, and Dr J H C Stevenson On its publication in the preceding August it was known that the inquiry was incomplete, the belief being current that further developments would probably be announced at no distant date

Discussion on the Report

The discussion on this report, which is summarised in the present article, was opened at the Statistical Society's rooms by Dr Reginald Dudfield on Nov 19th at the request of the council, who rightly judged that his experience as chairman of the special committee eminently fitted him for the task It is due to Dr Dudfield to state that, in addition to the ordinary duties of the chair, he undertook the whole of the correspondence, colonial and foreign as well as British on the result of which the report was eventually framed Of the magnitude of this task an idea may be formed from the fact that forms of inquiry were forwarded to the statistical authorities of not fewer than 136 States, and that replies have been received, tabulated and analysed, from 106 of that number[2]

In all inquiries of this nature the importance of accurate definition is obviously paramount, but in the present case it is astonishing that the committee were unable to discover among the returns furnished by the colonial and foreign authorities evidence of the adoption in any country of a real definition either of "stillbirths" or of "stillborn", the few authorities that have made the attempt having formulated expressions which lack the essentials of precise definition In these circumstances the committee, whilst considering it inadvisable to adopt any one of the definitions before them, declared it to be imperative that an international definition of stillbirths should be authorised and that all stillbirths should be registered They further incorporated in their report a memorandum prepared by Dr Dudfield, containing his personal suggestions with regard to the definition of the terms "stillbirth" and "stillborn," the committee adding the opinion that "those suggestions may serve as a useful base for future discussions"

Having perused the report and also Dr Dudfield's comments thereupon, we think that he acted discreetly in confining himself almost ent

The Question of Definition

Reverting to the question of definition—the only part of the report that has provoked criticism—Dr Dudfield said that when attempt is made to express in scientific language the condition popularly known as "stillbirth"—i e, the birth of a dead child—a difficulty is encountered as to the connotation of the several words "child" "birth," "dead," each of which requires some form of definition or descriptive paraphrase With reference to the exact meaning of the word "child," he inquires whether it is to be understood as applying to every product of pregnancy without regard to duration, or whether it should be limited to a fœtus which has attained a development that will enable it to maintain an existence apart from the maternal structures Questions of this kind obviously involve important points of law as well as of medicine Accordingly, Dr Dudfield quotes legal authority[3] for the statement that "life" begins as soon as an infant is able to stir in the mother's womb The first movement or "quickening" takes place in the fourth month of gestation, but the fixing a date for the beginning of "life" does not prevent unauthorised induction of abortion at an earlier date from ranking as criminal On the other hand, the physician relies mainly on auscultation of the fœtal heart sounds for evidence of life in utero For reasons specified in the text Dr Dudfield holds it preferable to date fœtal life from the time when the heart sounds become audible The middle of the seventh month of pregnancy is the period when a child is generally regarded as viable, and it is important to note that the Notification of Births Act does not require intimation of the birth of a dead child occurring before the twenty eighth week of pregnancy

In common parlance a child is held to be "dead" when it shows no signs of life But the question of what physical or other functions are to be taken as signs of life remains undetermined According to present legal practice a child is deemed to have "lived" when it has been proved to have breathed or cried after birth On the other hand medical experience shows that sometimes a liveborn child dies without making any respiratory effort We agree with Dr Dudfield in thinking that some test other than respiration should be adopted to distinguish live from still-born children

Suggested Definitions of "Stillbirth"

For the foregoing and other specified reasons the following conclusions are arrived at (1) That the term stillbirth should be limited to the product of gestation which has lasted for not less than 28 weeks, (2) that a birth is "complete" at the moment when the whole of the body of the child—"body" including trunk, head, and limbs—is outside the body of the mother, and (3) that the crucial test of "life" should be the continuance of the action of the child's heart

With the object of arriving at a definition which should be precise and simple, and at the same time suitable for international use Dr Dudfield applied to the council of the Obstetrical Section of the Royal Society of Medicine for an authoritative definition of the term "stillbirth" In response, he received from the honorary secretary of the section the following amended definition, which has been approved by the council of the section —

A stillborn child means a child which measures more than 13 inches

Respecting this definition Dr Dudfield observes that it is in close agreement with one whi
the only difference being the inc
and "breathing" which he had
note to the definition relegates such signs of life to their proper position, and practically reduces the proposed definition to the terms originally suggested except for the substitution of the length of the child's body as the test of the duration of pregnancy—a substitution which he personally approves

With reference to the registration of stillbirths Dr Dudfield remarks that the replies received from abroad to the question whether these are registered as births as deaths, or as both reveal a marvellous variety of practice For the study of ante natal causes producing stillbirths it is necessary that the latter should be regarded as deaths, and a medical certificate of cause of death should be invariably insisted on. Once the cause is known, it should not be beyond human ingenuity to suggest the remedies. In this way Dr. Dudfield believes it possible to reduce infantile mortality to limits considerably below what can be reached by present methods. By such means he thinks that the present shortage of new lives resulting from the lower birth-rate will be amply compensated.

Discussion of Proposed Definitions.

Most of an enteresting discussion has hovered round the definitions already suggested. Dr. Major Greenwood, recognising the difficulty of arriving at an exact definition of "stillbirth," hesitated to characterise the heart beat as the basal sign of life; indeed, he doubted whether any one basal sign of life existed. Taking the matter as a practical one, he suggested the question whether if the beating of the heart were considered the ultimate criterion, an appreciable number of children would be saved who, by the breathing and crying test, would be regarded as born dead. He thought that a much wider statement, not of the natuie of a definition, was, on the whole, safer and calculated to avoid the introduction of a provision which might not be effective in the case of untrained persons.

Dr. Amand Routh, commenting on the general meaning of the term "stillbirth," thought that it should include abortions as well as children born after the viable age of 28 weeks. From the view-point of preventing deaths in both periods of intra-uterine life, he thought it desirable to secure notification not only after, but also, if possible, before the age of viability. In addition to being compulsorily registered, they should also be included among the livebirths and the deaths. He expressed the opinion that most of the children who died in utero before the commencement of labour perished during the last few days of gestation, and that if the causes of such deaths could be determined many lives might be saved by inducing labour before the time of the probable fœtal death.

Dr. Walter Griffith communicated to the meeting some of the reasons why the council of the Obstetrical Section recommended the definition before them. They held that what was needed was a definition as accurate as possible, but sufficiently simple, so that it could be applied by anyone present at the birth, and by registrars and lawyers as well as by medical men. Such definition must be a compromise between utility and scientific accuracy. The length of the child was taken as the indication of its sufficient development, because anyone with a tape measure could measure the baby with accuracy. The alternative in common use was to speak of so many months or weeks of development, but it was not always possible to ascertain accurately the duration of gestation. With regard to the definition as a whole, he preferred that recommended by the Obstetrical Section to the amended one of Dr. Dudfield.

Dr. Butler, addressing himself to the question of evidence of livebirth, concurred in the view that a sign easily observable should be taken as crucial, and thought it convenient to take obvious signs like respiration, because this was a new function established at the birth, whilst circulation went on previous to birth and merely continued afterwards. It was because an arbitrary standard was necessary, and because the establishment of breathing was readily ascertainable, that it was desirable to continue the existing practice of assuming independent life only after the establishment of that function.

The discussion summarised above was a valuable contribution to the important subject dealt with in the report.

SIR SQUIRE BANCROFT'S READINGS.—Sir Squire Bancroft, whose readings in aid of hospitals were interrupted by ill-health last winter, now proposes to bring them to a close and to give a farewell "reading" of Dickens's "Christmas Carol," to complete as his gift to hospitals by this means the sum of £20,000. Sir Squire Bancroft's first public reading was in aid of the Middlesex Hospital, and he will give the final one in London for the same great charity in which he has long been interested, having served on the weekly board for 25 years. The reading will take place on the afternoon of Tuesday, March 11th, at the St. James's Theatre, which has kindly been lent for the purpose by Sir George Alexander.

Public Health.

REPORTS OF SCHOOL MEDICAL OFFICERS.

Hampshire County Council.—Dr. R. A. Lyster's well-considered and well-presented report deals with a school population of 52,700 and a total of 47,985 examinations and re-examinations. In the three years 1909–1911 there have been at least 80,000 examinations apart from those required by the code, and a very large proportion of all the children in the schools have now been inspected. Dr. Lyster emphasises the point that in relation to statistics the "really important figures are those relating to amelioration." Such a mass of statistics has now been accumulated as to make it desirable to minimise this side of the work as much as possible with a view to the larger expenditure of energy in more practical and hygienically profitable ways. The schools in Hampshire are divided into the two groups of urban and rural. The urban children show a preponderance of defects. Since the last year's report was issued with remarks concerning the superiority of clogs over ordinary boots, clogs have been adopted in many parts of the county. The progress of the work generally is shown to be very satisfactory, opposition from parents may be said to have practically disappeared; many of the boards of guardians have requested reports upon boarded-out children, and in some instances a member of the board attends at the time of inspection *in loco parentis*. Dr. Lyster urges that breathing lessons should be carried out every morning and afternoon, and that open-air teaching should be much extended. Some interesting pages deal with amelioration and the position of boards of guardians in relation to treatment of school children is considered at length. The report closes with a paragraph suggesting the advisability of the withdrawal of the system of payment of grants for attendance made by the Board of Education.

Bradford City Council.—It is pleasant to notice that a large part of the report of Dr. Lewis Williams is taken up with the consideration of ameliorative measures. The reports of the school clinic, of the school dentist, and of the open air school take up a large share of space, while another substantial section treats of methods of dealing with tuberculosis among school children, and recommends a schoo sanatorium for 50 children with accommodation for the teaching of another 100 non-resident selected cases. The provision of an open-air day school for 180 pre-tuberculou and early tuberculous children is also advocated. Th report includes a section devoted to the results of the inspection of secondary schools. Here the most notable fac which has been brought to light is the startling number of girls who suffer from spinal curvature, over 14 per cent. of the scholars in attendance being affected. A large majority of the cases are found curable by means of suitable remedial exercises. The school clinic has dealt with 7719 children needing treatment: 5064 received treatment and 1710 were referred elsewhere, while 945 were examined on account of scarlet fever or diphtheria before their return to school. The attendance was 1000 in excess of that for 1910. The total number of attendances made by children at the clinic for treatment and for examination was 20,325.

Salop County Council.—Dr. James Wheatley's report for 1911 lays stress on the preventive side of school inspection work, and expresses the view that the greatest result will be the decrease of dental caries. The report also emphasises the extreme importance of physical exercises in improving the health of children. The number of schools dealt with is 279, comprising 340 departments The children on the register numbered 32 491 in February and 33,086 in November, and during the year 7117 children were completely examined, of whom 1340 (18·8 per cent.) required medical attention. A greater percentage of defects was found in town as compared with country schools. There was also noted an excess of measles in town schools, but not of whooping-cough. The percentage of all children suffering from measles before the end of school life was 77·1 males and 79·8 females, 10 per cent. have scarlet fever, and 3 per cent. diphtheria. Both the latter are more prevalent in town than in country schools. The excess of defects is particularly well marked in eye cases; in town schools the percentage is 15·7 of children examined and in country

schools 10 5 The difference is ascribed to the conditions of town life, and among these the earlier age at which town children begin school, the lesser opportunity for outdoor life and the greater opportunity for reading It is suggested that one of the causal factors in the development of *adenoids is almost constant exposure to infection in* schools A useful leaflet for distribution has been dr wn
up dealing with mouth breath
exercises, this is reproduced
mine the influence of mouth-breathing on the production of dental caries, no marked correlation is observed Much valuable matter on other possible causes of dental caries is *included, and a leaflet with directions for the avoidance of* caries is reproduced Apart from a subscription of £76, and the provision of letters of recommendation for the Eye, Ear, and Throat Hospital for Shropshire and Wales, the education authority does not help financially in

in 1910

Cheshire County Council —The county of Cheshire is divided for medical inspection purposes into East, West and Mid Cheshire In these divisions 18,968, 20,769, and 20,057 children are in average attendance In recording the percentage of dental defects, one of the three inspectors notes only 18 children out of 6970 as requiring treatment The explanation is that the medical inspector concerned only issues notices to parents if the caries is accompanied by oral sepsis or sequelæ thereof And, speaking of the causes of caries, Dr Meredith Young considers it "a matter for regret that the quill toothpick has been banned by society" In Mid Cheshire only 1 in every 760 children showed any signs of having had conservative dental treatment The report contains the result of a valuable investigation into the cases of 84 mentally defective children by Dr A M Pryce, classified and analysed under 28 headings, also the *tabulated family history of 28 cases by the school medical* officer The medical inspector for West Cheshire (Dr G A Jubb) records the results of the examination of 78 dull, 25 backward, and 10 mentally defective children, and gives in diagram form two illustrative pedigrees Four school nurses are employed and the part-time services of 71 district nurses are also made use of, and the arrangements for "following up" cases have

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS

IN the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census, and whose
middle of this year is estimated
2 births and 5906 deaths were
ended Saturday, Feb 1st The annual rate of mortality in these towns, which had been 15 4, 16 5 and 17 0 per 1000 in the three preceding weeks, further rose to 17 2 per 1000 in the week under notice During the first five weeks of the current quarter the mean annual death rate in these towns averaged 16 4, or 0 5 per 1000 below the average rate recorded in London during the same period The death rates last
k in the several towns ranged from 4·9 in Devonport,
in Ilford and in Southampton, 10 0 in Ealing, 10 3 in
thport, and 10·5 in Wallasey, to 25·0 in Darlington, 25 6 in Barnsley, 25 9 in Wakefield and in Rotherham, 26 8 in Aberdare, and 31 5 in St Helens

The 5906 deaths from all causes in the 96 towns were 87 in excess of the number in the previous week, and included 430 which were referred to the principal epidemic diseases, against 526 and 505 in the two preceding weeks Of these 430 deaths, 205 resulted from measles, 66 from whooping-cough, 65 from infantile diarrhœal diseases, 62 from diphtheria, 17 from scarlet fever and 15 from enteric fever, but not one from small-pox The mean annual death rate from these diseases last week was equal to 1·3, against 1 5 per 1000 in each of the four preceding weeks The deaths attributed to measles, which had been 268, 277, and 275 in the three preceding weeks declined to 205 last week, and caused the highest annual death rates of 2 9 in Bootle, 3 2 in Barrow in Furness, 3 4 in Acton 6 8 in St Helens, and 6 9 in Wigan The deaths referred to whooping cough which had increased from 55 to 81 in the three preceding weeks fell to 66 last week and included 20 in London 10 in Liverpool, 3 in Nottingham, and 3 in Manchester The fatal cases of diarrhœa and enteritis (among children under 2 years of age), which had been 72, 87, and 67 in the three preceding weeks were 65 last week, 18 deaths were registered in London, 8 in
Birmingham 3 in Stoke on Trent and
The deaths attributed to diphtheria,
which had fallen from 64 to 47 in the three preceding weeks rose to 62 last week, 6 deaths occurred in London, 5 in Walthamstow, 5 in Bradford, 4 each in Portsmouth, in Birmingham, and in Manchester, and 3 each in Liverpool, in Sunderland, in Newcastle on Tyne, and in Rhondda The deaths referred to scarlet fever, which had been 32 25 and 19 in the three preceding weeks, further declined to 17 last week and included 4 in Birmingham 2 in London, and 2 in Aberdare Of the 15 fatal cases of enteric fever, which were equal to the average in the four preceding weeks, 4 were registered in London

The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospitals, which had steadily declined from 2112 to 1784 in the five preceding weeks, had further fallen to 1738 on Saturday last, 209 new cases were admitted to these institutions during the week, against 202 204, and 215 in the three preceding weeks These hospitals also contained on Saturday last 931 cases of diphtheria, 789 of measles 292 of whooping cough, and 40 of enteric fever, but not one of small pox The 1610 deaths from all causes in London were 67 in excess of the number in the previous week,
al to an annual death rate of 18 6 per 1000
ferred to diseases of the respiratory system,
dily increased from 285 to 393 in the six pre-
ceding weeks, further rose to 447 last week, and were 53 above the number registered in the corresponding week of last year

Of the 5906 deaths from all causes in the 96 towns last week 160 resulted from various forms of violence and 413 were the subject of coroners' inquests The causes of 51, or 0 9 per cent, of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest All the causes of death were duly certified last week in London and in its 14 suburban districts in Sheffield, Leeds, Bristol, Bradford Hull, Nottingham, and in 55 other smaller towns The 51 uncertified causes of death last

Attached to Units other than Medical Units.—Lieutenant Percy T. Tolputt to be Captain (dated Dec. 18th, 1912).

The undermentioned officers resign their commissions:—Captain Daniel O. Kerr and Lieutenant Alfred I. Shepheard-Walwyn (dated Feb. 5th, 1913).

PLAGUE PREVENTION IN KIAOCHAU.

In the *Archiv für Schiffs- und Tropen-Hygiene* for December, 1912, Dr. Uthemann, Surgeon-General of the German Navy, in medical charge at Kiaochau during the plague period in 1911, publishes an account, written in May, 1911, of the preventive measures taken at that time. Like all regulations, they were effective chiefly because they were very accurately carried out by a zealous and attentive staff; but Dr. Uthemann is of opinion that their usefulness is vouched for by the fact that no case of plague did occur in the capital Tsingtau, and he does not think the regulations could be materially improved. As any invasion by plague would have seriously damaged the trade of Tsingtau it was decided to keep the disease at all costs at a distance, rather than to arrange to deal effectively with cases as they arose. Accordingly, the whole frontier of the protectorate was policed, and the boundaries of the city protected by a barbed wire fence with a guard of apparently 300 men; the coast was patrolled by guard boats, and lighted at night by searchlight. In the wire fence were two openings, one only for admission, and near it a market where the buyers and sellers were separated by two wire fences 5 feet apart. As for the railway, a quarantine station was established at Syfang, where all passengers left the train and were examined and then kept under observation five days (many cases were found of typhus, typhoid, small-pox, and relapsing fevers). Responsible people who could be trusted were allowed to proceed and report themselves daily for five days to the police. If quarantined they were examined twice daily, and if without means were fed as well as housed. Quarantine of seven days was imposed on ships; that was, it is thought, a little long. The disease was so infectious, and in Manchuria destroyed so many doctors, attendants, and gravediggers, that it was necessary to protect the eyes with motor goggles, the mouth and nose with a cotton-wool mask, and to wear a hooded suit like that of the Mizericordia in Florence, with gauntlets and long boots. When leaving the ward the physician or attendant was sprayed with sublimate solution, his suit brushed with that to destroy any adherent germs; then he took the suit off and dropped it into more lotion, and so, having protected himself and others, he could go free.

THE DOSE OF VERONAL.

To the Editor of THE LANCET.

SIR,—The question has recently been raised as to the amount of veronal which may be taken without fatal results, and the following case may therefore be of interest Mr. ——, aged 20, was under treatment on account of recurrent attacks of vomiting, associated with a dilated stomach, and he had a very poor appetite. These attacks of vomiting had been present for many years past from time to time, and his appendix had been removed some two months previously. On Jan. 14th, 1908, he had returned home to the country extremely exhausted, and had had a hot bath in the afternoon and afterwards fell asleep. Towards night he complained of intense vertical headache and took tabloids of veronal at frequent intervals with the object of relieving it. He took altogether 56 grains. When seen the next morning by Dr. Crawley and Dr. Woollerton they found that he was suffering from some kind of poisoning, but they were at first uncertain as to its nature. The pupils were widely dilated, but reacted slightly; the knee-jerks and plantar reflexes were present, and he was in a semi-conscious condition. He was very ataxic, and did not recognise people; he was wandering in his talk, and slept the greater part of the day. He was almost pulseless, his heart's action was extremely feeble and intermitted at times and was rapid. On the 16th he was better, but was still drowsy and semi-conscious. He was very ataxic, and when he attempted to walk he staggered about and had to be supported. During the night he was seized with four epileptiform convulsions, but did not foam at the mouth. He was rigid; there were no tonic contractions. After these attacks he was very much exhausted; but on the 17th he was better, sitting up in bed and talking, and taking an interest in what was going on. He had, however, another slight convulsion in the morning, in which there was twitching, and his respirations were rapid, about 50. He complained of cardiac pain, and was very violent. He then passed into a condition of exhaustion in a semi-drowsy state. He was quite on the *qui vive* at the slightest noise, and wanted to know to what it was due; but he had no recollection of his attacks during the night, and he felt as if he was dying. On examination nothing abnormal could be made out. He was perspiring freely, the pupils were of medium size, and the tongue was clean. On the 18th he had two fits, and is said to have been amblyopic for a short time. There were no further symptoms, and he gradually recovered. I am, Sir, yours faithfully,

Portland-place, W., Jan. 29th, 1913. G. NEWTON PITT.

PROGERIA AND ATELEIOSIS.

To the Editor of THE LANCET.

SIR,—In his article with the above heading in the last number of THE LANCET, Professor Arthur Keith hopes that the publicity given to these remarkable disorders may result in the recognition of further cases, and that thereby additional light may be thrown upon their nature.

As I have devoted a good deal of attention to these two morbid conditions, I hope I may be permitted to emphasise his request. Indeed, it is difficult to over-estimate the importance of getting all the information about them that can be obtained. No one can read Professor Keith's searching comparison between acromegaly, progeria, and ateleiosis without being convinced of their intimate relationship, and in some measure realising the importance of the careful research which he is giving to them. They are not only interesting for their own sakes, but even more interesting because of the light their study may be expected to throw upon the nature of other disorders. It can scarcely be an exaggeration to say that anyone who gives an adequate explanation of their pathology unlocks the door to a complete understanding of the processes of normal growth and development, as well as of many diseases which are now among the enigmas of medicine. As we read Professor Keith's article, and bear in mind the work that is being done by others in the same field, we seem to be on the verge of discoveries which in course of time will place growth and development as much under our control as is the case with the initiation of offspring or the nutrition of the body. The importance of knowledge of this sort, in these days of the progressive weakening of the influences which make for the physical evolution of civilised man, can hardly be gainsaid. It is fortunate that there should now be a representative skeleton of each of the three disorders in the Museum of the Royal College of Surgeons of England. Evidently Professor Keith inclines to the view that the seat of the morbid state is in each case to be traced to some alteration in quantity or quality of the secretion of the pituitary gland. In this respect his opinion nearly coincides with that which has been formed by Cushing as expressed in his important book, "The Pituitary Body and its Disorders." But striking as is the evidence now being accumulated in favour of the pituitary origin of these maladies, much yet remains to be done before their pathology can be regarded as settled. It is still possible that the disease of the pituitary is either terminal or reciprocal and not primary. To suggest that five such striking, or even hideous, diseases as gigantism, progeria, acromegaly, Froehlich's combination, and ateleiosis are all of pituitary origin is to throw a heavy burden of responsibility upon one very small gland. And though this can hardly be regarded as an argument against the pituitary hypothesis, it must add to the *onus probandi* of those who adopt that view. On the other hand, the theory that the pituitary disorder is incidental, not essential, has at least the merit of priority. Whatever the explanation may be, the difficulties which surround the subject can only be overcome by further knowledge, and it is greatly to be hoped that Professor Keith's demonstration may result in the discovery of hitherto undetected examples of progeria and ateleiosis. I am, Sir, yours faithfully,

Reading, Feb. 1st, 1913. HASTINGS GILFORD.

THE PATHOGENICITY AND VIRULENCE OF BACTERIA.

To the Editor of THE LANCET.

SIR,—In a letter appearing in your issue of Feb. 1st Dr. E. C. Hort and Dr. W. J. Penfold drew attention to the importance of their work on temperature variations in animals produced by the injection of substances suspended in water. At the same time they criticised some of our recently published work, and wasted a lot of pity on us and numerous other workers in the same field. We might mention that at the time of our experiments we were fully alive to their work, and anticipating their criticism took full precautions to guard ourselves against error. The main points of their criticism are the use of guinea-pigs and the method of obtaining the water used.

With regard to the former, we found in our preliminary work that guinea-pigs that had become accustomed to the laboratory and which were kept with a constant supply of food maintained a very constant temperature, of course, having the normal diurnal variations. We drew no conclusions from single observations of rises within the ordinary limits. With regard to the other part of the criticism, the experiments on protein and bacterial fever are all in series, and the same amount of vehicle was used in each case as in Friedberger's experiments, and so at any rate the series are comparative, the same (?) error occurring throughout. Dr. Hort and Dr. Penfold's experiments are also capable of another interpretation, which we drew attention to at a meeting of the Pathological Section of the Royal Society of Medicine. Further, we should like to know the amount of calcium obtainable from a Pasteur Chamberland filter, which is made of aluminium silicate, by a water containing practically no carbon dioxide.

We are, Sir, yours faithfully,
F. H. THIELE,
DENNIS EMBLETON.
Weymouth street, W., Feb. 1st, 1913.

ARTIFICIAL RESPIRATION.

To the Editor of THE LANCET.

SIR,—If Dr. Leonard Hill will read the verse before the ones he quotes from 2 Kings iv. he will find that Elisha was alone with the child. The account of the miracle must therefore have come from Elisha, for the child could hardly have described what took place. If Elisha had blown into the child's mouth, surely he would have said so. The account does not say that the child began to breathe, but that "the flesh of the child waxed warm." The narrator evidently thought that the child was restored by some transference of vital force, and, as he was also the practitioner, I do not see how we can read anything else into the story. I much doubt if artificial respiration is consistent with the views of physiology held by Elisha, and I do not think he would like the practice to be associated with his name.

I am, Sir, yours faithfully,
Silverton, Devon, Feb. 4th, 1913. O. CLAYTON-JONES.

To the Editor of THE LANCET.

SIR,—Dr. Leonard Hill asks in THE LANCET of Feb. 1st, in referring to Elisha raising the Shunammite's son (2 Kings iv. 34), why is not this, the best method of restoring a child, called Elisha's method of artificial respiration? I would suggest in reply that it has not been so called because it has been included amongst the number of the miracles performed by Elijah. Verse 32 states: "And when Elisha was come into the house, behold, the child was dead, and laid upon his bed." This is confirmed by 2 Kings viii. 5, where Gehazi, the servant of Elisha, is relating the miracle to the King, "And it came to pass, as he was telling the king how he had restored a dead body *to life,*" &c. *Bible commentators have suggested that Elisha* so stretched himself upon the child in order probably to afford a channel for the Divine influence to pass. But to put the consideration of this aside for a moment, it is probable that in any case the "method" should be credited to Elisha's predecessor, Elijah, for in 1 Kings xvii. 21, Elijah, in raising the son of the widow of Zarephath, "stretched himself upon the child three times, and cried unto the Lord, and said, O Lord my God, I pray thee, let this child's soul come into him again."

I am, Sir, yours faithfully,
Feb. 3rd, 1913. SEARCHER.

THE MEDICAL PROFESSION AND THE NATIONAL INSURANCE ACT.

To the Editor of THE LANCET.

SIR,—At the annual general meeting of the National Medical Union, held on Jan. 28th last, it was resolved to convert the Union into a permanent organisation for medical men who decline service under the National Insurance Act as at present constituted. There is no other association at present which is definitely pledged to serve the interests of such men, or which might be of use as a rallying point for those who retire from service in the future.

Amongst the objects at which the Union is aiming are the following: 1. The bringing together of all those whose convictions have led them to remain in opposition to the present Act. 2. Mutual assistance amongst members all over the country. 3. The guarding of the interests of the members in every possible way. 4. To endeavour to uphold the honour and interests of the profession, which have been—and still are—gravely imperilled by recent events. 5. To secure efficient medical attendance for the industrial classes at reasonable remuneration.

It is hoped that all medical men who are in sympathy with the aims and objects of the Union will see their way to becoming members. The annual subscription is 10*s.* 6*d.*

I am, Sir, *yours faithfully,*
J. WEBSTER WATTS, Secretary.
5, John Dalton-street, Manchester, Feb. 4th, 1913.

To the Editor of THE LANCET.

SIR,—As there has been some misunderstanding about the *validity or non-validity of medical certificates* issued by non-panel doctors to insured persons, I have brought the matter before the Commissioners, who have sent me the following courteous reply:—

National Health Insurance Commission (England).

[illegible]

I am, Sir, your obedient servant,
(Signed) E. HACKFORTH.
The General Secretary, Medical Defence Union.

The profession will, I am sure, be glad to know what is the actual position in this respect.

I am, Sir, yours faithfully,
A. G. BATEMAN, General Secretary.
Medical Defence Union, Trafalgar-square, W.C., Feb. 4th, 1913.

To the Editor of THE LANCET.

SIR,—There has been a question of ethics before the profession, and it has by common consent been referred to the British Medical Association, acting formally through their Representatives. The decision is that anyone who after Jan. 18th joined the panel, or before that date, whether acting according to his own judgment, or induced or "coerced" by force of circumstances or other influence, is to be regarded as having acted rightly. There can, I take it, be no other meaning.

1. It was stated in my hearing that a member of a hospital staff who had joined the panel had been requested by his colleagues to give up his hospital appointment. 2. Enclosed are handbills circulated in Kensington. As my name appeared on the panel at the post offices, they refer to me, as well as to others some of whom may still be members of the Association. The intention is evidently to injure, professionally and pecuniarily, those whom the Association has justified. In serious matters relating to professional conduct we were wont to look to the *Royal College of Physicians* of London. This seems a situation calling for their interference.—I am, Sir, yours faithfully,

GEORGE C. CRICHTON, M.D. Edin.
Longridge-road, S.W., Feb. 4th, 1913.

SANITATION AT SEA.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

(Continued from p. 339.)

THE NEW FRENCH LAW AND THE NEW FRENCH SHIPS.

The One-class Boats.

THE new category of passengers that has come into existence is increasing rapidly now that a new class of ships has been built for their accommodation. These are the second-class passengers travelling on ships where there is no first-class. This is a natural development, since wealthy people constitute only a very small minority of the populations concerned. Far more numerous is the great professional and middle class—persons of good education and good social standing, but possessing only moderate means. When they need to cross the Atlantic they feel it humiliating to be railed off and kept in the after part of the ship, even though the second-class accommodation may be good; indeed, in some of the newest and largest Atlantic liners it is better in many ways than the first-class accommodation of a few years ago. In some of the German ships care is taken to make it impossible for the first-class passengers to see their second-class neighbours. Nevertheless, it is but natural to prefer the best part of the ship, and formerly the second-class traveller could enjoy this advantage only if he went by a cattle boat, where provision was made amidships for a few passengers at inexpensive rates. Such a prospect was not satisfactory, however, for the class of travellers that has recently come to the front. They need something similar in character to the first-class saloon passage, but less luxurious, and therefore less expensive. Thus expenditure in coal might be reduced, for they would be content with a slow boat, while the greater the speed, the more violent the shaking and the shocks received from high seas. After all, what does it matter if the journey takes two or three days longer. When there is every necessary comfort a holiday may be enjoyed as well on board as on shore. So long as the cabins are clean and cosy, it is as easy to sleep in a berth of enamelled iron as in one of highly polished and rare wood. Neither are costly silk furnishings and ornately carved and gilded ceilings necessary; good taste is not necessarily costly. On the other hand, travellers of this class are just as anxious about drainage and ventilation as are any saloon passengers. Knowledge of hygiene is a matter not of wealth but of education, and medical men and school teachers are better educated as a class than men who have made fortunes in business. Again, the former class can dispense with an orchestra at meal-times and for concerts. Nor do they require extravagant articles of diet, such as fruit out of season, or game, or caviare. But they do want a skilful *chef* and good food served without stint. And further, they want to drink the ordinary wines, white and red, which to-day are so cheap, and a cup of black coffee to round off their meals with, without extra charge. They need ample space on deck, a comfortable lounge, and a smoking-room or *café*—in fact, every facility for social intercourse and such games as can be enjoyed on board. All this is just what the Compagnie Générale Transatlantique attempted to supply when it constructed the *Chicago* and the *Rochambeau.*

The New Crowd.

As the demand for this sort of accommodation was met, so has it increased. For the moment it is essentially an American and French development. If we exclude those who travel on business, there is more to tempt Americans to Europe than Europeans to America. Further, it is especially the well-educated and well-read American who longs to visit Europe. Prominent among this class are the members of the medical and the teaching professions. Till recently many have been debarred from visiting Europe because they could not afford the first-class or saloon fares, with their incidental expenses, and did not care to occupy an inferior position as a second-class passenger. But in these new boats such passengers occupy the first position in absolutely the best part of the ship. In the fast liners the minimum saloon first-class fare varies from £18 to £25, while in the one-class boats the minimum fare, with privilege of the entire ship, is £11 on the *Chicago*, £12 on the *Rochambeau*, the maximum fare not exceeding £14. The result is that young medical practitioners, who most need the education of travel but whose income as yet is inadequate for the expensive saloon fares, are now coming over freely. The principal difficulty is—and this applies more especially to teachers and professors—that the latter can absent themselves only in the summer; consequently the ships are then apt to be unpleasantly crowded. Thus I found last November that no less than 400 berths had already been retained for the sailings announced to take place next June. The rush to Europe is from the last ship in May to the first ship in July, and the returning crowd sails from August 15th to Oct. 15th. At those periods every berth is occupied, wherefore the general sanitation, and especially the ventilation, of these ships becomes a matter of prime importance. As at least half the passengers who profit by this opportunity are connected with education, the ships sailing at this season are now known as *les bateaux scolaires*, or the school ships.

The Good Effects likely to Ensue.

There is also another cause of travel which may develop considerably. In New York especially the summer weather the excessive damp heat, is very trying. Many business men who cannot afford to leave their offices, nevertheless endeavou to send their wives and families to the mountains or the seaside during the worst months. But this is extremely costly, and many can ill afford the outlay. On the other hand in the less frequented parts of Germany, France, or th Ardennes good board and lodging can be obtained for 4*s.* a day especially if a contract is made for a large party. Moreover a substantial saving can be realised by the purchase of clothes in Europe instead of in America—I am not talking abou shopping in the Rue de la Paix or in Bond-street. Finally, a the Atlantic can now be crossed with all necessary comfor for a reasonable sum, the New York business man of moderat means finds it actually cheaper for his wife and family t spend the summer in Europe than at an American watering place. The one-class cabin, as this service is sometime called, is such a success that many more ships of the sam sort are likely to be built; and as this cannot be done fas enough, some of the first-class ships—*La Touraine* for exampl —have been converted into the one-class cabin, that is second class, style of ship. This evolution will be fraught with man consequences. In Europe we shall have an opportunity o making wider acquaintance with the American people, and th unpleasant impression produced by some of the vulgar ric will, in a measure, be counteracted by the welcome presence o the less wealthy members of the intellectual class. In th same way, as the latter class of visitors is naturally bette able to observe, appreciate, and to learn, it will carry bac to America those impressions that tend to forward th interests of civilisation at large. All these consideration while bearing on a multitude of questions, clearly show tha there will be in the near future a great augmentation o Atlantic passenger traffic, so that the sanitation of ship acquires increasing importance.

Experiments with Thermotanks.

It was in the spring of 1908 that the *Chicago* made he maiden trip. She is a ship of 11,105 tons and 9500 horse power, and can accommodate 314 second-class and 114 third-class, or steerage, passengers. The crew numbers i all 231 men. To provide healthy quarters for 1700 person in one single structure, even on land, is no easy matter, and at sea the difficulties become intensified. Of more recen construction than the *Provence*, the *Chicago* and th *Rochambeau* are better ventilated. They do not depend only on the extracting power of ventilating fans. The *Chicag* has 15 thermotanks, which are generally employed t pump warmed air into the cabins. The total electric force required to move the fans of these thermotanks is equal t 62 brake-horse-power, and they are supposed to delive 3,850,000 cubic feet of air per hour. The pressure of steam for heating is equal to 37 lb. per square inch, and the temperature 230° F. Experiments have been made as to the heating powers of these thermotanks. Thermotank No. 1 is credited with delivering 255,000 cubic feet per hour. Its air trunk is 64 feet long and supplies two decks. When the outside temperature was 52 F. the temperature in the forecastle was 104° F., in the emigrants' quarters 96° F., and in the hospital, on the lower deck, 100° F. But with thermotank No. 2 going down three decks, while the air at the start was 114° F., it had fallen to 86° F. at the farthest point of an air trunk of 70 feet in length. The longest air trunk is 100 feet, and it may be said that from the thermotank the heated air loses about 20 per cent. of its heat before it reaches the farthest end of the air trunk. Therefore those who like heat should get cabins as near as possible to their thermotank. But if these cabins become overheated and the inlet is closed, then there would be more warm air delivered in the cabins that are not so hot because they are farther off. Indeed, the passengers themselves, by watching the temperature of their cabins and controlling the inlets, might very materially help to assure a more even distribution of heat.

The Impossibility of Automatic Ventilation.

It was on Dec. 14th last that I sailed homewards on the *Chicago*, and during the journey had many conversations with the chief engineer about all these difficulties. It was mid-winter, just when the Atlantic was troubled by a succession of exceptionally severe storms. Everything that could be closed had to be fastened as tightly as possible to keep out the tempestuous waters. There was very little opportunity for natural ventilation, except for the great air shafts that abut on the upper deck by the funnels and feed the engine-room and stokehole. It is not the storms, however, but the rapid changes of temperature that render the heating and ventilating matters of such great difficulty. The chief engineer said that the ship passed from the Polar current, where the water was at 34° F., to the Gulf stream, where the water was at 73° F., in the space of not more than an hour. Automatic regulators only followed a change of temperature, turning heat off or on. What was necessary was to anticipate such sudden changes of temperature so as to obviate their effects. This, he said, could be met only by a very watchful and intelligent staff. The passenger did not complain until some time after he had been suffering; this could be prevented only by commencing to cool the ship before the hot stream was reached, and to heat it before it penetrated the Polar stream. No system of ventilation would work by itself; it required forethought, watchfulness, and experienced guidance.

In the Cabins.

On visiting the different parts of the ship I was much impressed by the forecastle. Here the effect of the recent legislation was distinctly visible. Each sailor had more space for his berth; 123 cubic feet is the legal minimum. Then there must be an inlet and an outlet for the air, together with proper means of warming as well as of ventilating. Here we had a thermotank just the same as that supplied to the most luxurious state-rooms. Consequently, the air was sweet and there was an appearance of comfort and brightness which constituted a great improvement on what I have too often seen on old-fashioned ships. The numerous hospitals on board were well supplied with natural and artificial light, and there was plenty of space. There are hospitals for women and for men, for infectious cases, for persons under observation, a pharmacy, and an operating-room. On visiting the steerage and the third-class cabins I found that the remarks I made in my last communication in regard to the *Provence* apply equally to the *Chicago*. As for the state cabins, an air-shaft goes through them all, and the passengers can open wide or partially the louvred inlet by which they receive air, warmed in cold weather, from the thermotank. Near the ceiling and the floor there are apertures, so that the air from the cabins finds its way into the passages, where more or less natural ventilation carries it out. If the full complement of four persons sleep in these cabins they must be somewhat cramped for space. But this rarely happens, and on the *Rochambeau* the cabins are larger. Cabins should be a little longer than the beds, so that at the end there may be space for hanging up clothes, for little handbags, or for some small drawers. To pull a heavy cabin trunk from under the berth for every little trifle wanted during the voyage is somewhat trying, especially if the weather is so rough that the trunks have to be lashed in their places to prevent their being thrown across the cabin.

Art of the Chef: Hygiene of the Kitchen.

Of course, I did not fail to visit the *chef*. All the officers on board were particularly proud of their culinary colleague and felt how much the success of the French line depended on the choice of its *chefs*. At the time of my visit the ship's [illegible]

His bookshelf was well filled: there was a culinary *encyclopædia*, and among many other books quite a large volume devoted solely to the cooking of eggs. In answer to my questions, the *chef* explained that when he was employed by a British company he was not allowed to cook as he thought proper, for the English passengers could not appreciate delicate flavouring. One of the best dishes he ever made, a specially prepared *pâté*, was too tasty for the saloon passengers, and the greater part had to be eaten in the kitchen and by the crew. Judging from my experience on the *Chicago*, it seems that *gourmets* will have to travel on second-class boats to find the operators who know their trade. On these one-cabin boats there is compulsory dining. The passengers are not given the opportunity to feed badly, as in the first-class saloon. They are not allowed to order tasteless dishes and to eat them in the wrong order. Nor are they allowed to eat too quickly. Meals—lunch of four courses and dinner of five courses, properly ordered, flavoured, and artistically cooked—are served in due order, at very cheap prices. Further, though we had a fierce storm lasting three days and were pitched about unmercifully, I noticed comparatively little seasickness. Finally, I must add that the kitchen is well-ventilated and constantly cleaned out. The cooks have the necessary facilities for washing and keeping themselves clean, and my observation showed that they availed themselves of these sanitary advantages. Such are some of the reasons which assure the growing success of this new phase of ocean travel. But while it increases the frequency of inter-oceanic intercourse, it also augments the responsibilities of those who control the sanitation of the floating towns that now so frequently cross the broad and turbulent expanse of the Atlantic.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

National Medical Union a Permanent Organisation.

THE annual general meeting of the National Medical Union was held in Manchester on Jan. 28th, Mr. William Coates presiding. Mr. F. H. Westmacott introduced a motion, which was seconded by Dr. J. Brassey Brierley, proposing that as a temporary organisation the union should cease to exist, and that it should be reformed into a permanent organisation of men who decline to allow their names to appear on the Insurance Act lists or panels, and who refuse to work the Act until the conditions of service are acceptable and conformable to the honour and dignity of the profession. It was felt that it was necessary to have a union to support non-panel men and to be a rallying point for those who might retire from service of the Act at any time. The motion was carried. The following rider was added to meet the case of men who, it was reported, intend shortly to retire from the panels:—

[illegible]

A Bishop on the Insurance Act and the Medical Profession.

The Bishop of Manchester, speaking at Manchester Cathedral on Sunday night, paid a tribute to the medical profession. He said that so strong is the faith that the causes of disease are not beyond our control, that he did not hesitate to say that if a physician were given an opportunity to choose between the power of working miracles as our Lord did and the power of discovering, for instance, the cause of cancer, he would undoubtedly choose the latter. The Bishop expressed his opinion of the attitude of the doctors to the Insurance Act in the following terms:—

> It has appeared to some people as though the whole grievance has been a dispute over sixpence; but, so far as I can judge, they have desired only to secure that the work under the Act shall be thorough [illegible] poor should be regarded as
> the same careful attention [illegible]
> intended strongly that their [illegible]
> the judgment of people who [illegible]
> really fighting the battle of [illegible]

the poor, and they deserve the gratitude of the nation for the endeavour which they have made to secure the conditions under which medical service in the end should be a reality and not a sham. This, at all events, has been my impression of the controversy, and, in justice to the profession, I feel bound to record it.

Hospitals and dispensaries will continue to be necessary—at least for the worst and most needy cases. For the present, at all events, the Insurance Act has not diminished the work of the hospitals; they will still need to be supported. They will still afford an opportunity of bringing charity and science, love and knowledge, in touch with one another and with the poor.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Changes at the University and at the School of Tropical Medicine.

Dr. J. W. W. Stephens has been appointed to the Alfred Jones chair of tropical medicine, vacant through the resignation of Sir Ronald Ross. Dr. Stephens has been connected with the Liverpool School of Tropical Medicine for the past ten years. During the last few years he has held the Walter Myers memorial lectureship. He graduated as M.D. at the University of Cambridge in 1898, and at one time held the John Lucas Walker studentship of pathology at that University. In 1897 he was appointed assistant bacteriologist to the Government of India, and was subsequently made a member of the Royal Society's Malaria Commission in Africa and India. He has taken an active part in the teaching work of the Liverpool School of Tropical Medicine, and has published much valuable research work upon tropical diseases. Dr. George Lissant Cox, assistant lecturer in pathology at the University, has been appointed chief tuberculosis officer for the county of Lancaster. Dr. Cox was an ardent worker in the Thompson Yates laboratory. He served for three years on the staff of the Liverpool Consumption Hospital, so that he is well equipped for the duties of his new post. The departures from Liverpool of Sir Ronald Ross, Professor F. G. Donnan, and Dr. Lissant Cox will create a blank in local medical circles not easily filled.

The late Dr. William Carter.

Dr. William Carter, who died on Feb. 2nd after a short illness, retired from practice about five years ago, when he removed to Deganwy. Dr. Carter's connexion with the honorary staff of the Royal Southern Hospital extended over 30 years, and he was for a long time a leading figure in the medical world of this city.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Presentations to Sir Thomas Chavasse.

ON Jan. 30th the board and staff of the General Hospital and other friends expressed their appreciation of the able manner in which Sir Thomas Chavasse has performed his duties as honorary surgeon for the past 30 years, by the presentation of a three-quarter length portrait of himself in oils to be hung in the board-room of the hospital; of another of her husband to Lady Chavasse; and of an illuminated address to Sir Thomas Chavasse. The Lord Mayor, Lieutenant-Colonel Martineau, presided over a large company. Mr. J. B. Clarke, chairman of the presentation committee, in presenting the portrait, which was executed by Mr. A. T. Nowell, to be hung in the board-room, said they desired to do honour to a most worthy Birmingham citizen, the possessor of a good old family name well known and highly revered in the Midlands. They all deplored his absence as the result of an accident in the hunting field and wished him a speedy recovery. After studying in Edinburgh, Birmingham, Dublin, Vienna, and Berlin, he became assistant surgeon to the hospital in 1877, and in 1881 was elected a full surgeon, and so remained for 31 years. No one outside the walls of the hospital could have an adequate idea of the magnitude and scope, the self-denial, the anxiety, courage, patience, industry, and skill required for the post. If the governors could not have Sir Thomas Chavasse with them in that room they were determined to have the best reminder they could of him and his noble work. The portrait, which represents Sir Thomas Chavasse wearing the gown of a Fellow of the Royal
[illegible] en unveiled, and accepted
[illegible] . Sir John Holder next pr
to Lady Chavasse a portrait, the gift of the 171 subscr
the fund. He remarked that they were also indebte
Thomas Chavasse for having inspired that great bene
to Birmingham, Miss Ryland, a near relative to Lady Ch
to bequeath £25,000 to the hospital. He was also
mental in obtaining other large donations, and himse
£1250 for the endowment of a bed. Mr. Gilbert
next asked the Lord Mayor to present an illuminated
to Mr. Arthur Chavasse on behalf of his father.

The Death of Lord Ilkeston.

Although Lord Ilkeston for some years had ceas
actively engaged in medical practice in Birmingham,
a very well-known figure in the city, and had been co
physician to the General Hospital since 1890. He fir
to Birmingham at the age of 20 to take up the appoi
of medical tutor at Queen's College and assistant p
at the Queen's Hospital, and in 1868 he transfer
services to the General Hospital, where he was ma
physician. He took a very active part in local
organisation, which prepared the way for the great
played afterwards in the British Medical Associati
also served his apprenticeship to politics in th
council in the early Chamberlain days. He will al
remembered as a great Birmingham citizen. His s
succeeds to the title, is stipendiary magistrate to the

THE trust funds accumulated in accordance with
of the late Mr. Robert Irvine have now reached the
£30,000. The income from £25,000 of this is to be
salary for a Robert Irvine professor of bacteriolog
University of Edinburgh, and the remainder of this
ment is to be employed for the equipment of class-ro
laboratories in connexion with the new chair.

Edinburgh Medical Committee.

A meeting of the medical profession in Edinbu
held on Jan. 29th at the Society of Arts Hall, an
decided that a local Medical Committee should be a
to watch over medical interests in connexion with t
ing of the National Insurance Act, and to advise
Edinburgh Insurance Committee upon medical questio
meeting then elected a committee consisting both o
tioners upon the panel and of those who are no
application is to be made to the Scottish Insuran
missioners for recognition of this body in accordan
the terms of the Act.

Memorial to the late Dr. G. A. Gibson.

A meeting was held last week at the Royal Co
Physicians of Edinburgh, under the chairmanship
President, Dr. J. J. Graham Brown, to consider the
tion of a memorial to the late Dr. G. A. Gibson.
decided, upon the proposal of Dr. Byrom Bramwell, se
by Mr. J. W. B. Hodsdon, that a memorial should be f
and a committee for this purpose was appointed.

Dr. G. A. Gibson and the University of St. Andr

The University Court of St. Andrews have record
deep regret at the death of their former co
Dr. George Alexander Gibson, and their sense
great loss caused thereby to science, medicin
Scottish culture. "They recognise," says the
of the meeting, "how great was his distinc
a physician, an original investigator, and a
and accomplished writer on many branches of
cine. They recall with thankfulness his valuab
vices as a member of University Court, and the c
kindness, courage, and courtesy which he showed in
relations of life They grieve over the bereavement
widow and family, and direct that a copy of this mi
sent to them as an expression of sympathy."

Aberdeen Eye Institution.

At the annual meeting of subscribers to this ins
the report of the directors drew attention once ag
the unsatisfactory state of the accounts, althou

expenditure had been cut down to the minimum, representing only 2s 2d per case treated (including 2197 operations, and the cost of keeping 53 in-patients with an average stay in the institution of 30 days each). Dr. A R. Galloway in his report stated that workmen treated minor eye injuries far too lightly, frequently using dirty instruments—such as pins—for the removal of foreign bodies, and they often continued work after receiving an injury These were the cases which resulted in septic ulcers, with frequent impairment and sometimes loss of vision The large fall in the number of school children affected—1387 for the previous 12 months—led him to hope that school inspection was having a desirable effect. The report further stated that there were about 1700 men employed as stonecutters in Aberdeen and district One out of every two received medical aid for eye injuries every year, and out of a total of 809 eye injuries to stonecutters in Aberdeen during one year 645 were treated at the institution Principal George Adam Smith acknowledged the very great benefits which the University derived from the institution In doing so, he recalled that the institution owed its origin in a large measure to the University itself, having been founded in 1835 by two eminent University men, Sir James McGregor and Dr Cadenhead

Gray's Hospital, Elgin, and the National Insurance Act

At a meeting of the Elgin town council held on Jan 27th the matter of a resolution of the managers of Dr Gray's Hospital, Elgin, in connexion with insured persons was discussed It was stated that the funds for the erection of the hospital were left by Dr Gray in 1807 for the express purpose of treating the sick poor of Elgin The resolution of the managers of the institution recently published in the newspapers seemed to stultify this aim, and the following *resolution on the matter was adopted by the meeting after* some discussion —

> The council, in view of the intimation that the trustees and managers of Dr Gray's Hospital had passed a resolution that no insured persons under the Insurance Act will be entitled to receive treatment at the hospital except in cases of emergency, unless an arrangement is made for payment to the managers of the hospital of £2 2s per week as an indoor patient or £1 1s per week as an outdoor patient, and considering that under *Dr Gray's* settlement the town council had power to inspect the hospital and state to the trustees and [illegible] may observe resolve to remit to the law [illegible] orsyth added thereto, to consider the [illegible] the trustees and managers and if so [illegible] to them to have their resolution withdrawn or at least amended

A great deal of feeling has been aroused in the town of Elgin over this matter

IRELAND.

(FROM OUR OWN CORRESPONDENTS)

Evidence of Sickness for the Sickness Benefit

IN the Civil Service Supplementary Estimates for the year ending March 31st next a grant of £50,000 is provided for the Irish National Health Insurance Fund towards the cost of medical certificates of sickness and other administrative expenses arising out of the absence of medical benefit in Ireland. To what expenses other than the provision of evidence of sickness and disablement this grant can be applied is not clear The certificate question is a source of trouble both to the insured and to the medical profession The profession has agreed on a uniform charge of 2s. 6d for certificates, but so far the societies and Insurance Committees, though for the most part they demand a medical certificate as evidence of sickness, have made no arrangements to pay The Act puts the onus on the societies, which endeavour to transfer it to the member Medical men are consequently put in the difficult position demanding the fee from the applicant, who is often unable to pay In many instances such members are deprived of the benefit to which they are legally entitled At a meeting of the practitioners of South Tipperary, held in Clonmel last week, a resolution was unanimously passed declaring it an unprofessional act for any medical man in the district, either in private or Poor law practice, including workhouse hospitals county infirmaries, or other hospitals, to give certificates for sick benefits to insured persons pending a final settlement of the question In most cases, however, medical men are demanding the 2s 6d fee, leaving the member to recover it from his society, as the only way by which the societies can be caused to make suitable arrangements The additional grant of £50,000 ought to make such arrangement easier. In the attempt to obtain other than medical evidence as proof of sickness some societies have adopted strange expedients In Dublin lay inspectors, said to be nurses, have visited the sick, even in hospital wards, and examined the patients and the hospital records, while in a village in the south a railway porter is engaged in his spare time as a lay inspector, and has carried out his duties to the extent of examining a girl's knee

The Corporation of Dublin and Tuberculosis

At a conference last Tuesday between the public health committee of Dublin corporation and the county borough Insurance Committee the most pressing problem was the upkeep of the Collier Dispensary, now subject to the public health committee, but for which no provision has been made in the city estimates The Insurance Committee were asked to transfer to the public health committee almost their entire income, the latter body undertaking to provide for all classes of tuberculosis No scheme has yet been drafted, but a joint subcommittee probably will shortly be appointed to draft one The corporation possesses a dispensary, and is in joint possession of a sanatorium, and it is understood that some of the Treasury grant to which it is entitled will be spent in providing accommodation for advanced cases It hopes, therefore, soon to be in a position to give the Insurance Committee any form of treatment it may desire The Insurance Committee probably will meantime advance a small sum to meet the pressing needs of the Collier Dispensary

Dinner at the Royal College of Surgeons

The Charter Day dinner of the Royal College of Surgeons was held last Saturday, Mr R D Purefoy, the President, being in the chair Before dinner the honorary Fellowship of the College was conferred on Surgeon General Sir W Launcelot Gubbins, Director-General R A M C, and Sir Berkeley G. A Moynihan Among those who spoke to the various toasts after dinner were the Lord Lieutenant, the president, vice-president (Mr F Conway Dwyer) and honorary secretary (Sir Charles A Cameron) of the College, the two new honorary Fellows, the Rev J P Mahaffy, and Dr James Little

The National Insurance Act in Belfast

The Belfast Insurance Committee has made a satisfactory arrangement with the Local Medical Committee for a temporary scheme of domiciliary treatment of tuberculous patients, which has been confirmed by the Irish Insurance Commissioners, but the Committee has so far been unable, on financial grounds, to arrange with the chemists For the post of tuberculosis medical adviser Dr Foster Coates was chosen by the Insurance Committee out of three names submitted Great dissatisfaction has been expressed in medical circles in Belfast at the active canvassing that was practised by some candidates for the post

The Belfast Corporation and the Tuberculosis Problem

The public health committee of the Belfast corporation is at present considering a scheme for dealing with the whole question of tuberculosis, and conferences are taking place between the members of this committee and a sub committee of the Local Medical Committee A statement has been submitted on behalf of the latter body for the consideration of the Belfast public health committee with a view to a satisfactory settlement

Typhoid Fever in Belfast

[illegible]

traced to any known common cause, such as milk, or water, or the eating of shell fish The only point common to all the cases is the insanitary condition of the houses in which they have occurred, yet it is not clear why this factor should operate during wet weather when it was apparently non-existent in the dry summer of 1911 There are over 20 cases in Purdysburn city fever hospital at present

The Forster Green Hospital for Consumption

At the annual meeting in connexion with the Forster Green Hospital for Consumption, held in Belfast on Jan 30th, it was reported that 261 in patients were admitted during 1912, and 979 new out-patients were seen. The evil effect of the Insurance Act in curtailing subscriptions, due to the expenditure enforced on all employers under the Act, was mentioned, and apprehension was expressed as to the future effect of the Act upon the work of the hospital.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Antityphoid Inoculation in the Navy.

ON Jan. 20th M. Roux laid before the Academy of Sciences a communication from M. Chantemesse, in which the fact was recalled that the struggle for pure drinking water had been going on for 25 years. It was not, however, always possible to secure pure water, and, moreover, the prophylactic problem was not entirely confined to this factor. From its inception bacteriology had sought to discover a vaccine against typhoid fever. In 1887 Fraenkel and Simmonds, Bauer and Peiper, showed that by injecting into animals small doses of living and virulent typhoid bacilli, their resistance to the virus of typhoid fever was augmented. This inoculation with living non-attenuated microbes was, however, too dangerous to admit of its application to man. M. Chantemesse, in conjunction with M. Widal, then made known a typhoid vaccine, consisting of typhoid bacilli sterilised by heat, which was harmless, and yet three or four injections of which conferred on animals immunity against the virus in the great majority of cases. On its application to man it was found to confer a like immunity on him. In 1896 this vaccine was tried in the service of M. Chantemesse on his pupils, and little by little its use was extended to other countries. After a year's trial on soldiers vaccinated with the heated vaccine the United States made this prophylactic procedure compulsory in the army. In 1903 Wassermann extolled the polyvalent bacillary vaccine and also the autolysates, which method has been recently taken up in France. In 1909 M. Chantemesse called on the Academy of Medicine to appoint a committee to study this method of prophylaxis against typhoid. After a favourable report from the Academy the Minister of War instructed M. Chantemesse last year to institute, in conjunction with a *médecin principal de l'armée*, this method of vaccination among the troops on the Algerio-Moroccan frontier. In Morocco no vaccinated person was attacked with typhoid. M. Chantemesse has always stedfastly adhered to the method of preparing the vaccine by heat sterilisation, and preserving it in a creosote emulsion, which prevents its subsequent accidental contamination. On April 5th, 1912, the Minister of Marine, M. Delcassé, authorised the systematic vaccination of the crews of the navy and the workmen at the dockyards with M. Chantemesse's vaccine. The chief of the navy medical department has recently communicated to M. Chantemesse, with the authority of the Minister, the results of the vaccinations practised among the crews of the three large squadrons and of the flying squadrons. The greater part of this marine population, some 67,845 persons, which had not been subjected to antityphoid vaccination, had sustained between April 5th and the end of December, 1912, 542 cases of typhoid fever and 118 cases of febrile gastric attacks. On the other hand, 3107 persons who had never had typhoid were vaccinated. These vaccinated individuals, who were on the same vessels as the non-vaccinated, were present in the same regions and were subject to the same conditions of work, of fatigue, of pleasures, and to the same chances of contagion, were protected against the disease in a very satisfactory manner, and did not incur a single case of typhoid. Only one man had a febrile gastric attack, which was cured. Similar information coming from widely separated parts of the world gives room for hope that little by little typhoid fever will entirely disappear from civilised countries.

Resection of the Large Intestine for Constipation.

In the case of a patient who consulted Dr. Pauchet for gastric ulcer, because of vomiting and pain supervening two or three hours after meals, X ray examination showed nothing abnormal in the stomach, but that the bismuth accumulated for two or three days in the cæcum. M. Pauchet, therefore, performed ileosigmoidostomy. The gastric trouble was reflected from the large intestine. The palliative result of the operation, however, was *nil*, the patient continuing to suffer with his stomach as before. The only effect was more frequent and softer stools. Radiography after the operation showed a reflux of part of the fæcal matter to the cæcum, where it stagnated for some time. In consequence of the persistence of the stomach trouble and the patient's consequent malnutrition, Dr. Pauchet operated again for the removal of the large intestine, having again found the stomach normal on examination. On laparotomy he found the cæcum and the ascending colon absolutely full up to the hepatic flexure, and he removed the cæcum, ascending and transverse colons, stopping at the descending colon. The operation was very easy. The peritonisation of the denuded surfaces presented no difficulty. The abdominal wall was sutured in one layer with a bronze suture. The patient was out of bed on the fifth day and left the hospital on the fourteenth.

Hygienic Delivery of Bread.

As an instance of the increasing attention that is being paid to hygienic matters, it may be mentioned that M. Herriott, the mayor of Lyons, has pointed out that the open delivery of bread, as in baskets, barrows, and the like, exposes it to contamination with dust and filth. He has therefore issued a decree that loaves delivered by any other method than in a closed vehicle must be completely wrapped in an impermeable covering.

The Purification of Oysters by Retention in Filtered Sea Water.

Of late years those who are fond of oysters have been exercised over various accidents, such as typhoid fever, that have ensued on eating them. Measures of various kinds have been taken in certain places to prevent such accidents, but complete security has not yet been attained. M. Budin and M. Chevrel have made some experiments on the purification of oysters from bacteria by keeping them in filtered sea water. On Jan. 13th they reported the constant and clear results obtained, which fully confirm those of M. Fabre-Domergue. After six days' retention in a current of sea water capable of renewing the entire contents of the vessel every two hours, the microbic purification of infected oysters in the marble container was complete in every case, and particularly with regard to the bacillus coli. At the end of this time the oyster had undergone no changes that could depreciate its market value. In a second series of researches the experimenters verified the disappearance of the typhoid bacillus under like conditions from oysters that had been artificially infected. The process of retention in filtered sea water in a sand filter without submergence, invented by M. Fabre-Domergue, may thus afford a simple solution to the problem of protecting oysters against bacterial contamination.

Feb. 3rd.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Salvarsan.

Dr. Kren, in a paper read before the Medical Society in Vienna recently, summarised the results of careful observations made on 285 patients who suffered from syphilis and were treated with Professor Ehrlich's salvarsan. These patients, whose cases were followed up for a long time (over two years), received more than 600 injections of the remedy. In the year 1911, at the Clinic Riehl in Vienna, whence this report comes, a combined treatment of syphilis was introduced, consisting in an injection of 0·4 gramme of salvarsan, followed up by 30 inunctions with mercury ointment, these being immediately succeeded by another injection of 0·4 gramme of salvarsan as the final stage. The effects of this method were much better than those previously obtained. The general result of these investigations was summarised as follows. Salvarsan was a powerful remedy against syphilis, changing the course of the disease. It was not only useful in the primary stage, but was able to prevent the occurrence of secondary manifestations if employed early enough, before the serum reaction became positive; but the glands remained in the same state as at the time of injection, showing thus the symptoms of latent syphilis. Such cases have remained free from further complications for over two years In the secondary stage the remedy was less successful, but the important matter was either to give repeatedly increasing small doses or to combine the injections with inunctions of mercury Large single doses of salvarsan were not to be recommended The tertiary and the hereditary manifestations of syphilis were very successfully influenced by salvarsan *If care was taken and the contra* indications attended to there was no danger in its use These contra indications included the existence of (1) any disease which was aggravated by increase of the blood pressure , (2) all grave affections of the nerves ; (3) non-syphilitic diseases of the inner and middle ear, as well as occupations which injured the ear by the noise they produced , (4) all diseases of the glands which might cause a breaking down of them ; and (5) localisations of syphilis which might endanger life if they became swollen by the Herxheimer reaction as for instance, in the trachea or on the laryngeal articulations Dr Kren stated emphatically that fear to use salvarsan in relapses of a syphilitic disorder of the auditory nerve was not justified He said that in cases of syphilis not treated with salvarsan the auditory nerve suffered just as frequently as when salvarsan was given and the symptoms in question were promptly remedied by the use of it

Professor von Noorden

Professor von Noorden, the famous specialist for diseases depending on disordered metabolism is said to intend leaving Vienna and returning to Frankfort, where he will continue to practise untrammelled by clinical duties By the end of this year he will therefore no longer occupy his present position Energetic efforts are being made to induce him to alter his decision, but they have hitherto been unsuccessful

Psychological Experiments for Forensic Purposes

The discrepancies of statements made by witnesses in courts of law are well known as is also the fact that it is hardly possible to get several identical correct descriptions *of occurrences if details are required* The Psychological Juristic Society of Vienna recently had an instructive ordinary meeting in which this subject was tested A few weeks before this ordinary meeting there had been a special meeting in which one of the members, after a quarrel, applied abusive epithets to the president The whole thing had been prearranged, and the respective parts of the two principal actors had been well studied by them according to a written text Of course, nobody knew anything of the arrangement except the few who took part in the simulated quarrel Two weeks after the incident had taken place all members of the society were *asked to give verbally or in writing their evidence*, and a regular hearing of the case was held in the ordinary meeting, with two real judges and two barristers for the prosecution and defence When the witnesses gave their evidence, it was found that although well educated intelligent people were present at the supposed quarrel, not one of the statements made by them was correct Even as regards the duration of the episode and the time of occurrence, there were large discrepancies in the statements Acting on the evidence of the witnesses, the accused person, who was a lawyer holding the title of doctor of jurisprudence was pronounced guilty The written text of the whole affair was then read aloud and compared with the statements made *by the witnesses whereupon it appeared that the account of* the "quarrel" given by the eye witnesses and others who were present on the occasion in question were unreliable in numerous points, and that in reality the incident had taken place in a way which would have exculpated the accused This experiment showed how much the influence of excitement might be detrimental to exact perception of facts following each other in rapid succession

False Identification

The difficulty of relying upon a witness was observed quite recently here in a dramatic way when the body of a middle aged and unknown woman was found in a park A man positively declared the dead woman to be his wife, from whom he had been divorced two years ago She was accordingly buried as his divorced wife A few weeks later the woman who was really the divorced wife returned to Vienna, and was astonished at the declaration that she was legally dead In this instance the man's "identification" of the deceased woman received apparent corroboration from statements made by former friends of the wife, they being no doubt influenced by the husband's declarations

Feb 3rd

UNITED STATES OF AMERICA

(FROM OUR OWN CORRESPONDENTS)

Vital Statistics of the City of New York, 1912

Dr Ernst J Lederle, Commissioner of Health, reports that during the year ending Dec 31st, 1912, 73,008 deaths occurred, giving a death rate of 14 11 per 1000 population This number is less by 2415 deaths than that reported during the year 1911 and will probably compare favourably with that of any other large city in the world As compared with the decennial averages from 1902 to 1911 inclusive, typhoid fever *has decreased* 34 per cent , small-pox 95 per cent , measles 30 per cent , scarlet fever 38 per cent , diphtheria and croup 48 per cent , tuberculosis of the lungs 17 per cent , other forms of tuberculosis 11 per cent , while pneumonia (lobar and broncho) showed a decrease of 2678 deaths But the greatest gain is seen in diarrhoeal diseases under five years of age, a decrease of 2657 deaths Other decreases were in cirrhosis of the liver 266 deaths, in Bright's disease and nephritis 1114, puerperal diseases 206, accident 687, suicide 174 appendicitis 15, cerebro-spinal meningitis 604, and bronchitis (acute and chronic) 1042 Increased mortality was seen in cancer by 295 deaths, homicides by 57, organic heart diseases 1455 (offset, however, by a decrease of 1449 deaths from apoplexy and disease of the arteries) Mortality was decreased at all ages , in children under 1 year by 5159 deaths , under 5 years by 8463 , between 5 and 65, 7570 , 65 and over, 824 The decrease among the females reached 20 per cent , among males, 18 per cent The mortality among the coloured population was stationary There were 28 242 *deaths in institutions, a decrease of* 658, while the deaths in tenement houses numbered 30,579 a tremendous decrease of 12 781 The general death rate for the previous decennium was 17 37, so that the 14 11 of 1912 gives a decreased rate of 3 26 per 1000 population The infant mortality during the year was the lowest ever recorded in the city—viz 14 289 deaths, which gives a rate of 105 per 1000 births The number of births reported during 1912 was 135 625 an increase of 1083 over 1911 The birth rate for the year 26 22 per 1000, is the lowest since 1906 Stillbirths were reported as 6617, a decrease of 1379 on the decennial averages The number of marriages reported was 52,391, or 10 13, the highest marriage rate in five years

The Possibility of a National Health Department

It is confidently expected that the new Congress, to meet in March will make it possible to place in operation a National Health Department either independent of existing departments or as an adjunct to our active and efficient Public Health Service , while in New York the State executive is certain to advocate and push through the Legislature new laws, or amendments to those already in existence *amplifying the powers of the State Department* of Health, giving greater scope to officials, State and municipal, to enforce sanitary measures

Antityphoid Inoculation

Since the beginning of the year the New York City Board of Health has been prepared to inoculate all applicants gratis with antityphoid vaccine through its health inspectors either at the applicant s residence or at the central office of the department The vaccines will also be furnished free to practitioners *All requests for treatment must come through* the attendant or a medical inspector of the department This it is hoped with more effective control of the milk-supply, will practically put an end to typhoid fever

Eugenics

Eugenics generally forms an absorbing topic for discussion in both professional *and lay literature in America* The sane and humane power *behind this movement* is, however, less that of the numerous writers or the pseudo scientist than of those who are making comprehensive and exhaustive study of the question A propaganda of education is already taking place, which it is hoped may exercise a salutary influence on the law-makers.

Street Accidents.

During 1912, 532 persons were killed in street accidents in New York City, 230 of these being children. The number of persons injured was 2363.

A Typhoid Carrier.

The typhoid carrier, known as "Typhoid Mary," who was detained for three years on North Brother Island as a public menace by the New York Board of Health, and who brought a suit against the board, has been advised by the courts that she has no cause for action, as the board acted entirely within the power conferred upon it by the city charter.

Regulation of the Sale of Milk in New York.

The New York city department of health has recently issued a circular laying down rules for the sale of milk in the city. There will be three grades—A, B, and C. Grade A will comprise all milk suitable for the use of infants and children, and is to be sold only in bottles. Grade B is that suitable for adults, and will comprise pasteurised milk and selected raw milk, and may be sold in either bottles or cans. Grade C is milk suitable for cooking purposes only, and will be the poorest grade permitted to be sold. Bottles and cans must be clearly labelled to indicate to which grade the contents belong, the markings for each grade to be of a distinctive colour. Pasteurised milk must be plainly so marked. Only Grades A and B are allowed to be sold in restaurants, at lunch counters, &c., for immediate use by adults, while Grade A milk alone is recommended for children. Pasteurised milk is regarded by the department as safer than raw milk of the same grade.

The Mary Putnam Jacobi Fellowship.

The Woman's Medical Association of New York City offers the Mary Putnam Jacobi Fellowship of $800 available for post-graduate study, open to any woman graduate of medicine. The amount of the endowment to date will permit of a biennial award. Upon the completion of the fund this will be made annually. The Fellowship will be awarded, not by competitive examination, but upon proof of ability and promise of success in the chosen line of work. Applications for 1913-14 must be in the hands of the committee of award by April 1st, 1913, and must be accompanied by (1) testimonials as to thoroughly good health and (2) as to ability and character; (3) a detailed account of educational qualifications; (4) a statement of the work in which the applicant proposes to engage while holding the Fellowship; (5) examples, if any, of her work, in the form of articles, or accounts of investigations which she has carried out. The award will be made by June 1st, 1913, and will take effect from Oct. 1st, 1913, to Oct. 1st, 1914. All applications for this Fellowship should be forwarded to the committee of award, which consists of Dr. Emily Lewi (chairman, 35, Mt. Morris Park West, New York), Dr. Martha Wollstein, Dr. Mathilda K. Wallin, Dr. Helen Baldwin, and Dr. Emily D. Barringer.

Jan. 27th.

A POST-GRADUATE vacation course, open to foreign medical men, will be held at the Medical Clinic of the Hôtel Dieu, Paris, under the direction of Professor A. Gilbert, beginning on Monday, March 17th, and ending on April 1st. The subject of the course will be Recent Views on Diseases of the Liver, Pancreas, and Spleen. The course will consist of 24 lessons—two on each working day, at 10.30 A.M. and 3 P.M. respectively. The instructors will be Dr. Jomier, Dr. Herscher, Dr. E. Chabrol, Dr. Maurice Villaret, Dr. Lippmann, Dr. Bénard, Dr. Paul Descomps, and M. Deval, M. Guilleminot, M. Durey, and M. Dausset. There will be individual examination of patients and instruction in prescribing, the use of apparatus and laboratory work, all thoroughly practical, and a certificate will be given at the end of the course. The fees (100 francs) should be sent by post-office order to M. Deval, Chef de Laboratoire, Hôtel Dieu, Paris. In September a practical course on the Application of Laboratory Methods in Diagnosis will be held under the same conditions as in former years.

Obituary.

THE RIGHT HON. LORD ILKESTON, P.C., M.D. ERLANG., F.R.C.P. LOND., D.C.L. DURH., LL.D. MONTREAL,

FORMERLY PARLIAMENTARY SECRETARY TO THE LOCAL GOVERNMENT BOARD; CONSULTING PHYSICIAN TO THE BIRMINGHAM GENERAL HOSPITAL.

BY the death of Lord Ilkeston, which took place at his residence in London on the last day of January, the medical profession has lost its remaining representative in the House of Lords, Lord Lister having died last year. Lord Ilkeston did a mass of good work, both for his country generally and for the profession of which he was a distinguished member; and while it is impossible to consider that he won the rare honour of hereditary rank by his scientific position, he none the less owed his early recognition as a valuable public servant to his application of the teachings of medicine and sanitation to workaday life.

Balthazar Walter Foster was the eldest son of Balthazar Foster, of Beaulieu, Hampshire, and of Marion Green, Cambridge, in which latter town he was born on July 17th, 1840. He received his early education at Drogheda Grammar School and proceeded thence to Trinity College, Dublin. After studying medicine in Dublin at Trinity College and at the Royal College of Surgeons, he qualified L.R.C.P. and L.R.C.S. of Ireland in 1860, and almost immediately went to Birmingham, where he became medical tutor at Queen's College, and assistant physician to the Queen's Hospital. In 1864 he obtained the M.D. degree of the University of Erlangen, and became a Member of the Royal College of Physicians of London a year later. He was elected to the Fellowship in 1873. In 1868 he was appointed physician to the Birmingham General Hospital, an institution in which he took a keen interest, and with the practice and educational routine of which he was associated for so many years. He did not relinquish his active professional duties at the hospital until 1890, when he was appointed consulting physician. During this period of his career he did indeed much to reorganise medical education in Birmingham and, among other things, played a prominent part in bringing about the amalgamation of Queen's College and Sydenham College. He was elected Professor of Medicine in the College in 1868, retiring as Emeritus Professor in 1892.

Identifying himself with almost every phase of municipal life he entered the city council of Birmingham in 1883. As a member of the city council, on which he served for six years, he did excellent work for the health department, and, as had already happened before in Birmingham in the notable example of Mr. Joseph Chamberlain, he became marked out for public work of an important kind. It was seen that the talent which he displayed within the limits of municipal life would find a larger scope in general politics. He soon became one of the most prominent members of the local Liberal association, and in 1885 he successfully contested the city of Chester in the Liberal interest. Subsequently in the spring of 1887 he was returned for the Ilkeston Division of Derby, holding the seat until his retirement from the House of Commons in 1910, being one of the comparatively few fighting politicians who have been able to retain an unbroken hold on a constituency for over 20 years. From 1886 to 1890 he was chairman of the National Liberal Federation. In 1892 his work and influence were recognised by Mr. Gladstone, who in the Government formed that year selected Foster as Parliamentary Secretary to the Local Government Board. Foster was the first medical man to be appointed to a position in any political administration, and while his appointment was partly due to his political work in Birmingham, it was clear from the nature of the office which he was selected to fill that his medical position was not overlooked.

At the Local Government Board he was recognised by both sides of the House as a thoroughly able and conscientious administrator who had the welfare of the public and the progress of medicine always at heart. His professional knowledge, organising ability, and prompt application of his knowledge to the needs of the time enabled him to deal successfully with the outbreaks of cholera with which the country was threatened during his period of office, and it was partly in recognition of the

THE RIGHT HON. BALTHAZAR WALTER FOSTER, P.C., M.D. ERLANGEN, F.R.C.P. LOND.,
FIRST BARON ILKESTON.

(Reproduced from a photograph by Messrs. Elliott and Fry, Ltd., London.)

great assistance which he thus rendered to his country that in 1887 the British Medical Association bestowed upon him its gold medal for "distinguished merit" In the British Medical Association, within which from time to time he held almost every appointment, his activities on behalf of the profession found wide scope, and it was in this Association, as he himself said when in 1892 a dinner in honour of his appointment was given to him, that he received his chief training for public work On the return of the Liberal Party to power at the close of 1905 Sir Walter Foster was made a Privy Councillor, but he received no portfolio from Sir Henry Campbell Bannerman, an omission which was probably dictated by the necessity of finding room for a younger generation that had grown up in the Liberal Party during long deprivation from office, but which, none the less, elicited much comment

Foster's connexion with the British Medical Association was for many years, as has been already said very close When in 1872 the Association held its annual meeting in Birmingham he undertook the duties of secretary, and in 1884 to 1887 he was President of the Council In the section of Public Medicine at the meeting in Birmingham in 1892 he delivered the annual address, and dealt with the relations between the public and the medical profession so far as public health is concerned in the manner of one who knew—as an administrator and not as a visionary He pointed out that there could be no danger in a civilisation like that of Great Britain at the present day of medical tyranny or of the curtailment of individual liberty beyond that which was necessary in the interests of the public good for th [illegible] e, and if more such [illegible] days it is quite possi [illegible]

For [illegible] Direct Representative members for England on the General Medical Council He was first elected to the Council in 1886 immediately after the Medical Act had been amended to give registered medical practitioners the power of electing their own representatives, his colleagues being the late Dr J G Glover and the late Mr Wheelhouse On the Council his voice was heard attentively always—indeed, the first selections made by the medical profession of their Direct Representatives proved extremely happy The principle of direct representation was viewed by many on the Council with grave distrust, but the calm and sagacious assistance which that body received from Foster Glover and Wheelhouse completely answered the critics of a popular departure

In February, 1910, after nearly 25 years of active political work in the House of Commons he resigned his seat for the Ilkeston division, and in the summer of the same year his public services in and out of Parliament were rewarded by his elevation to the peerage The appearance of his name among the Birthday Honours gave great pleasure to the medical profession, whose interests he had never forgotten amidst the stress of political life He took his seat in the House of Lords as Baron Ilkeston, and was thus the second member of the medical profession to be created a peer For many years he was a justice of the peace for the county of Warwick, and in 1910 he was presented with the freedom of Ilkeston

Among the many academic distinctions which were bestowed upon him were the honorary D C L of the University of Durham, which he received in 1893, and the LL D of Montreal, which was conferred upon him in 1897 after the meeting of the British Medical Association held in that city He was also the first President of the Irish Medical Schools and Graduates Association

Land reform and the extension of small holdings were among the subjects in which he was greatly interested, and he was President of the Land Reform Association for several years and was also President of the Allotments and Smallholdings Association Although his life was so fully occupied in other directions he was a frequent contributor to the medical press, and was for some years a valued member of the staff of THE LANCET and of the *British Medical Journal* He also contributed to the literature of medicine both from the point of view of the treatment of disease and in the wider aspect of public health Among his published works were "The Use of the Sphygmograph in Heart Disease," "The Use of Ether and Etherised Cod-liver Oil in the Treatment of Phthisis," "Clinical Medicine," "Method and Medicine" "The Prince's Illness its Lessons," "Therapeutics of Diabetes Mellitus," "The Comparative Mortality of Birmingham and other Large Towns," "Diabetic Coma Acetonæmia," "Political Powerlessness of the Medical Profession," and "The Public Aspects of Medicine"

He married Emily, daughter of the late W L Sargant, of Edgbaston, and had four children His surviving son, the Hon Balthazar Stephen Sargant Foster, succeeds to the title The funeral took place at Brookwood Cemetery on Monday, Feb 3rd, and a memorial service was held at St Margaret's, Westminster, on the same day

---

JOHN FREDERICK JOSEPH SYKES, M D, D Sc EDIN,

MEDICAL OFFICER OF HEALTH OF ST PANCRAS

WE regret to announce the death, on Jan 28th, of Dr J F J Sykes the well known medical officer of health and authority on questions of public health and sanitation

Dr Sykes, who was in his sixtieth year, was born at Brighton, where he received his early education Subsequently he studied at Paris and Frankfort on Main and at Guy's Hospital, University College Hospital and in the University of Edinburgh, taking the English conjoint qualification in 1878 in which year he also graduated M B at Edinburgh University In 1880 he took the B Sc degree, and in 1893 the M D of his university He served for a time as resident medical officer of the French Hospital, but almost from the commencement of his career he devoted himself to the public health side of his profession He was for many years an assistant examiner in hygiene in the Science and A [illegible]

Dr Sykes s [illegible] improvement of [illegible] 1888 he directed public attention to the insufficient control over the burial and identification of deceased persons and the verification and certification of deaths, and in the following year brought to notice the lack of proper hospital accommodation for cases of diphtheria in the metropolis When [illegible]

danger of midwives spreading puerperal fever In 1895 he gave evidence before the Poor law Schools Committee on the spread of disease in barrack schools In 1901 he initiated the notification of chicken pox during the prevalence of small pox Among his colleagues in the public health service his opinion was very highly valued

Dr Sykes was a member of the Faculty of Medicine of the University of London and a Fellow of the Royal Statistical Society The latter body awarded him the Howard Medal in 1900 for a competitive essay on the Results of State, Municipal, and Organised Private Enterprise on the Housing of the Working Classes in London and other Large Cities He was also Milroy Lecturer at the Royal College of Physicians of London in 1901, when he took for his subject Public Health and Housing the Influence of the Dwelling upon the Health in Relation to the Changing Style of Habitation The suggestive and valuable lesson of those lectures was that the relief of the pressure of population would ultimately be brought about by the improvement of the means of transport between the suburbs and urban centres, the building of additional houses in the suburbs, the attraction to the suburbs of the better classes and those able to live at a distance, and the slow but ultimate relief of the pressure in the middle zone by the movement and circulation of the population and the gradual vacating of houses occupied by single families and sub-letting in separate dwellings The remedy for dilapidation and deterioration would be brought about by the reconstruction of the worst areas and houses in healthy flats, the adaptation of the best streets and houses of an unhealthy "floor" type to a healthy "flat" form of construction to suit the altered mode of usage, and the supplementing of sanitary laws and by-laws with the dwelling as the basic unit

A Fellow and member of the council of the Sanitary Institute, he for some years was co editor of the Transactions and a member of the board of examiners He was President of the Incorporated Society of Medical Officers of Health and a member of the Epidemiological Society, of the Société Française d'Hygiène of the Société d'Hygiène Publique de Paris, and of the Deutscher Verein für öffentliche Gesundheitspflege. At one time he held the position of lecturer on public health at Guy's Hospital. He was a member of the organising committee and honorary secretary of the Section of Architecture and Hygiene at the International Congress of Hygiene in 1891, and was a delegate to the International Congress of Hygiene and Demography at Budapest in 1894. To the literature of the subjects in which he was so much interested he added largely, and for ten years compiled the annual health reports of Middlesex. His numerous writings upon health subjects include a volume of the Contemporary Science Series on public health problems, and various essays and reports.

The borough of St. Pancras, for which he was medical officer for 28 years, having been appointed in 1885 in succession to Sir Shirley Murphy, owes him a deep debt of gratitude for the interest which he took in all that concerned its health and well-being. He was one of the founders of the St. Pancras School for Mothers. Not only St. Pancras, however, but the whole metropolis is indebted to him for his untiring activity in the cause of the health of the people, and the science of hygiene generally has been the richer for his life.

He married Jane, the daughter of Mr. John Reynolds of Brighton, and leaves a son and a daughter.

WILLIAM CARTER, M.D. LOND., F.R.C.P. LOND., F.R.C.S. IREL., J.P.,

CONSULTING PHYSICIAN TO THE ROYAL SOUTHERN HOSPITAL, LIVERPOOL, ETC.

WE regret to announce the death of Dr. William Carter, the well-known Liverpool physician, which occurred at Prince's-avenue, Liverpool, on Sunday last, Feb. 2nd.

Dr. William Carter was born at Newbury, Berkshire, in 1836, and received his medical education at Charing Cross and St. Thomas's Hospitals in London, and also in Dublin. At the University of London he had a distinguished career, winning gold medals in physiology and comparative anatomy, and obtaining honours in materia medica, organic chemistry, in medicine, midwifery, and forensic medicine. He also obtained medals from the Society of Apothecaries in London in botany, materia medica, and pharmaceutical chemistry. He graduated in the University of London as M.B., B.Sc. in 1864, having previously taken what was then the recognised double qualification of M.R.C.S. Eng., L.S.A. He was appointed demonstrator of anatomy at Charing Cross Hospital, and after a brief stay in Dublin, in 1866 he went to Liverpool, where he remained in practice and enjoyed close association with the scientific and educational side of the city for 42 years.

His first introduction to educational work in Liverpool was his appointment to the lectureship on chemistry at the Liverpool College in Shaw-street, Liverpool, and from that time he was associated with the academic life in the city dating almost from the beginnings of the existing University of Liverpool. He was promptly appointed physician to the Liverpool Royal Southern Hospital and later to the Liverpool Eye and Ear Infirmary, while he was also for a period medical officer of health for West Derby. This sanitary appointment, which he held for some time, though the other professional claims on him were very heavy, gave him that insight into sanitation which made him so prominent a social reformer. Upon the foundation of the University of Liverpool he became professor of materia medica and therapeutics, a post which he held till 1908, when, on giving up his professional work, he was made Emeritus Professor. For 36 years he was honorary physician to the Royal Southern Hospital, his term of service being specially extended after he had reached the age of 60. In 1908, when he relinquished professional practice and decided to retire to Wales, a farewell banquet was given to him at which a portrait of himself painted in oils was presented to him by his friends and admirers.

In addition to the purely professional duties implied in what has been recorded, it must be mentioned that Dr. Carter was always in the forefront in public controversies upon medico-social subjects. His efforts in the promotion of total abstinence were very energetic in Liverpool; he was an acute critic of legislation for the notification of infectious disease, and the measure under which we at present live records his views rather than the wider objects first aimed at. He was an ardent advocate of the formation of medical defence unions; he spoke from the beginning, with a conviction which many of his colleagues and friends did not, and do not, share, of the benefits that would unfailingly follow on the registration of midwives; he was once engaged in starting a journal having for its object the reform of the Contagious Diseases Act; and he was a strong public champion of efficient vaccination.

With one *cause célèbre*, the famous Maybrick case, he was intimately associated, and the accuracy of his remarks upon the trial, which were published in THE LANCET shortly after the sentence had been given, was unchallenged, despite their dealing with highly controversial points. Dr. Carter gave his reasons in one sentence for believing that the symptoms displayed by the deceased had resulted from an irritant poison, most probably from arsenic.

The memory of Dr. Carter's strenuous career as physician and social reformer, which is indicated in these notes, will long remain in the city where his life work was done.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Baby Bonus.

DISSATISFACTION has been expressed in Parliament that members of the medical profession were in some instances charging a fee for filling up the certificate by which the baby bonus is claimed. The Bill provides that a medical certificate must state the child was viable, if there is any reason to doubt the fact. The Prime Minister said that for doctors to charge for these certificates was "unprofessional." The general practice has been not to make any specific charge for the certificate, but to raise the midwifery fee. On the other hand, many medical men contend there is a principle involved, and that raising the midwifery fee does not properly cover the charge for filling up a certificate. The Women's Hospital authorities now detain £3 of the £5 from their patients for a fortnight's treatment.

Lady Talbot Milk Institute.

Some months ago the Victorian Government requested Dr. J. Johnston, of the Board of Public Health, to draw up a scheme by which a pure milk-supply for infants might be extended. He proposed that various municipalities should with assistance take over and extend the operations of the Talbot Institute. The municipalities have not responded except in a very few instances. The financial state of the Lady Talbot Milk Institute once more is such that Government aid is to be invoked.

Sydney Tuberculosis Dispensary.

It is stated a report has been presented to the Chief Secretary giving information of the above institution. In the three months of its existence 250 patients are said to have been treated "with satisfactory results." A somewhat more startling allegation is that of 40 "contacts" who submitted themselves for examination, half of them were found to be suffering from consumption. These figures are apparently accepted by the dispensary officials, who point to them as sufficient justification for the existence of such work. But in some quarters they are doubted.

Friendly Societies in Victoria.

The annual report of the Government statist of Victoria (Mr. A. M. Laughton) on Friendly Societies shows a steady increase in membership and funds. At the end of 1911 there were 48 societies, with 1498 branches, a total membership of 148,603, an annual income of £559,585, and funds representing in the aggregate £2,246,396. The funds per member worked out at £15 2*s.* 4*d.* The growth of the societies, both financial and numerical, has been especially marked during the last ten years. Between 1901 and 1911 the membership increased by 45,498, the annual income by £181,545, and the total funds by £875,792. At the close of 1911 there were in existence 11 female societies, having a membership of 11,056 and total funds of £32,321. Ten of these were associated with male societies. The membership of males at the end of 1881 was 49,431, out of a population of males of 16 years and upwards of 274,840. At the close of 1911, when the population had grown to 436,989, the male membership of friendly societies was 137,547. The ratios to population of annual income and total funds were greater in Victoria than in Great Britain, while the funds per member in Victoria exceeded by almost 100 per cent the proportionate funds held in Great Britain The mortality prevailing among Victorian friendly society members has been shown by recent investigations to be much lower than that of the general community This favourable feature is specially noticeable at the younger and middle ages Returns have been furnished this year for the first time by juvenile societies They show that at the end of 1911 the number of members of 35 branches of four societies who were entitled to benefits was 429, and the funds amounted to £1585 The following is a summary of membership, revenue, expenditure, and total funds during the triennial period 1909-10-11 —

	Membership	Revenue	Expenditure	Funds
1909	136,340	£523,871	£399,345	£2,012 417
1910	142,275	534 616	424 431	2 122 602
1911	148,603	559,585	435,791	2 246,396

Victoria has about 28 per cent of the branches of the Friendly Societies of Australasia, 28 per cent of the members, and almost 32 per cent of the capital

West Australian University

The following professorial chairs in the West Australian University have been filled —Biology, Mr A Willey, D Sc, F R S; chemistry, Mr N S Wilsmore, D Sc, English, Mr. W Murdoch, M A, mathematics and physics, Mr A D Ross, M A, D Sc, geology, Mr W G Woolnough, D Sc, mining and engineering, Mr H E Whitfield, B A, B E

Immigration Medical Inspection

The Federal Government is contemplating the establishment of a medical inspector of emigrants to the Commonwealth to reside in London The Melbourne *Argus* expressed some suspicion that this merely [illegible] tion by the Labour Party against [illegible] being conducted by various States [illegible] for External Affairs) has made a statement in answer to this idea He said —

> The suggestion is that a Commonwealth medical officer should be stationed in London, and it will be his duty to appoint in the various centres doctors who will be entitled to charge only a specified fee for examining anyone desirous of coming to Australia That examination will take place in the town or village in which the prospective immigrant lives A certificate issued by the local doctor will be sufficient to enable anyone to go on board a steamer Besides that, I do not see any objection to a person who has a family doctor being examined by him provided our representative is satisfied as to his credentials, and I am prepared to put that view before the medical man we appoint On the same conditions I am quite satisfied that the certificate of any well known doctor in England will be [illegible]
>
> [illegible] at a port en route Great Britain has been specially [illegible] being [illegible]
>
> [illegible] credentials are much more liable to be refused [illegible] Commonwealth when the final searching examination is made here

Medical Rhodes Scholar

The Rhodes scholarship in Victoria for 1912 has been given to Mr F R Kerr, who is a medical student in his fifth year

Melbourne City Health Officer

The city health officer's position, rendered vacant by the resignation of Dr J Jamieson, who has held it for 27 years, will be thrown open to application There is some difference of opinion whether applicants outside Australia should be barred The salary proposed is £750 per annum

Jan 2nd.

Medical News.

THE HUNTERIAN SOCIETY DINNER—The anniversary dinner of the Hunterian Society took place at De Keyser's Royal Hotel on Feb 4th, the President, Mr A H Tubby, being in the chair A large number of ladies were present, and the function undoubtedly gained much in festivity from their presence, which removed some of the sense of heaviness that occasionally broods over such gatherings at the commencement Dr T B Hyslop gave the toast of "The Hunterian Society," which was responded to by the President, who referred to it as the second oldest medical society in London, having been founded in 1819, and as being largely a society of Guy's, St Thomas's, and London men He briefly reviewed the work of the Hunterian orators Dr W Langdon Brown, in proposing "The Guests and Sister Societies,' thought it a good thing that the amalgamation of societies in the Royal Society of Medicine had not entirely crowded out all the smaller societies He pointed out that the Hunterian Society was not the second, but the third, oldest society in London, as the Abernethian Society intervened between it and the Medical Society He referred in graceful terms to the work of Sir Francis H Champneys, Sir W Watson Cheyne and Dr Arthur Latham, whose names he coupled with the toast Sir Watson Cheyne, replying for the Medical Society of London, referred humorously to the proposal of marriage that had been made a few years back but had been declined, and Sir Francis Champneys, as President of the Royal Society of Medicine, expressed his opinion that the Medical Society had done quite right in refusing the alliance for certain of the smaller societies performed functions which they would lose by amalgamation He looked forward to the time when the acknowledged function of the Royal Society of Medicine would be to express an authoritative opinion on all important subjects in medicine and surgery Dr Arthur Latham dwelt on the twofold advantages that accrued from learned societies—the increase of knowledge and the promotion of social intercourse He said it was not sufficiently known that the amalgamation of societies into the Royal Society of Medicine had been largely due to Sir Richard Douglas Powell Referring to medical research he announced that the Government had agreed to give no less a sum than £60,000 for that purpose Dr W J M Ettles in proposing the toast of "The Orator and Officers," said that the duty of the orator was to [illegible] and see [illegible] Hunter [illegible] Dr E W Goodall, [illegible] mith, in proposing the health of "The President," mentioned that they had had an interview with the Chancellor in reference to the National Insurance Act, and expressed his pleasure in being able to announce that as a result they were going to get something very good out of him after all The President replied The dinner was excellent, and excellent music, vocal and instrumental, was provided by Miss Gladys van der Beech, Mr Leon Fartovsky, Miss Adelina Leon, Mrs Fraser Henry, and Mr Bernard Jellen

REMARKABLE HEALTH RECORD AT PWLLHELI—At the last meeting of the town council of the ancient borough of Pwllheli (whose municipal charter dates back to the days of the Black Prince) some remarkable figures were submitted by the borough surveyor with reference to the health of the town During the month of December the death rate was only 6 31 per 1000 There were no cases of infant mortality During the year 1912 the death rate was 9 45 per 1000, as compared with 13 3, the lowest record for England and Wales The following comparative table was submitted —

1877-88	Death rate	21 7	per 1000
1895-1904	"	18 8	"
1905-12	"	17 05	"
1912	"	9 45	"

There was entire freedom from notifiable infectious diseases during 1912 The town has greatly increased in public [illegible] recent [illegible] rt Its [illegible] regoing figures, and the record is the more remarkable because a large proportion of the dwellings are very old and a high percentage of the population represents old people.

The foundation-stone of a new large hospital has just been laid in Bell Ville, Argentina, by Dr. Ernesto Bosch, Minister of Education. The building will cost $2,000,000.

The late Dr. W. Page May.—On Jan. 25th the organ and tablet placed in the English Church at Helouan, Egypt, in memory of Dr. Page May, were dedicated at a special service. Lord Kitchener, as trustee of the church, unveiled the tablet, which is a very beautiful one of alabaster and marble.

A New Appointment at the South Devon and East Cornwall Hospital, Plymouth.—The committee of the South Devon and East Cornwall Hospital recently decided to add the post of assistant physician to the list of appointments of the honorary medical staff of the institution, and as a result Dr. Colin Dunrod Lindsey has been elected to this new position.

Twelfth Congress of the German Society for Orthopædic Surgery.—This Congress will take place in Easter week, and the official date of opening is March 25th (the day before the meeting of the German Surgical Society), although a meeting for the display of lantern slides will be held on the previous evening at 8 P.M. The meetings will take place in the Langenbeckhaus, Ziegelstrasse, 10 and 11, Berlin. The President for 1913 is Professor Dr. H. Spitzy, of Graz (Glacisstrasse, 15). The chief subject chosen for consideration and discussion is the Treatment of Chronic Arthritis. On March 26th the members of the Congress will hold a joint session with the Section for Kinesitherapy of the Fourth International Congress for Physiotherapy. The principal subjects will be the Physical Treatment of Joint Disease and the treatment by exercise of Nervous Diseases. Communications with reference to this section should be made to Herr Professor Dr. G. Joachimsthal, Genthinerstrasse, 16, Berlin, W.

The Association of Public Vaccinators of England and Wales.—The annual dinner of this association was held at the Hotel Cecil, Strand, London, W.C., on Jan. 31st, Mr. Arthur Maude, the President, being in the chair. The occasion was marked by some exceptionally good speaking. Sir James Crichton-Browne and Surgeon-General G. J. H. Evatt, in replying for the guests, spoke in serious terms of the present position of vaccination in this country, owing to the popular ignorance of the real facts. Sir James Crichton-Browne frankly deplored the easy-going way in which the law allowed anyone on an ill-considered pretext to deprive the country of practical immunity from small-pox; while Surgeon-General Evatt insisted particularly upon the good that would ensue upon some regular system of popular education upon the whole subject of vaccination, supporting his words from his long experience both in the army and as President of the Poor-law Medical Association. Mr. Maude spoke in strong terms of the public apathy concerning vaccination and of the complete neglect of the scientific work to be done exhibited by the State. The Government, he said, did not help the important work of the Association of Public Vaccinators in any way. Their work, however, must be done, because what he might call the "red terror" was going to arrive some day. In Japan, Servia, Mexico, Russia, and Germany—indeed, all over the world—this was recognised, and the only place in ignorance was our own country. It was shameful that we should be the only people who did not prepare the nation for the "red terror." The unvaccinated people with us now amounted to some 50 per cent. of the population, and in many towns the proportion was worse. Isolation of cases as they arose might do a great deal in a limited outbreak, but the epidemic when it came would not be limited, and with a large proportion of our small-pox hospitals now allocated to other purposes we might find ourselves face to face with an overwhelming epidemic. Organisation and preparation against that time, which would come, was necessary. Mr. A. H. Martin, the retiring President, in proposing the health of the President, said that an outbreak of small-pox must sooner or later devastate this country, and a great responsibility rested upon the heads of Government departments. Vaccination exemptions had been allowed to go on throughout the land till they had increased in some places to something like 80 per cent. There were several other speakers, and the chairman briefly replied. The dinner was accompanied by a well-rendered musical programme.

The council of the National Association for the Prevention of Consumption have elected Sir Robert W. Philip, M.D., as vice-chairman of the council, in succession to the late Dr. Theodore Williams.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Grants in Aid of National Health Insurance.

Supplementary estimates just published give the details of the special grants in aid of National Health Insurance which the Government propose to vote before the end of the current financial year (March 31st, 1913). The total amount of the grants is £1,825,000. The details of the grants are as follows:—

National Health Insurance Fund (England)...	£1,380,000
" " " " (Wales)	101,000
" " " " (Scotland)...	214.000
" " " " (Ireland)	50,000
Special Drug Fund (Great Britain)	30,000
Mileage Fund (Great Britain, excluding the Highlands and Islands of Scotland)	50,000
Total	£1,825,000

The grants in aid made to the English, Welsh, and Scottish Insurance Funds will be applied by the several Commissions in grants by way of additional payments at a rate not exceeding 2*s.* 6*d.* for each insured person for the cost of medical attendance and treatment, and not exceeding 1½*d.* for each insured person for the cost of the administration of medical benefit. The Scottish grant in aid includes £10,000 for mileage and other special charges in the Highlands and Islands of Scotland.

The Irish grant in aid is to be applied towards the cost of medical certificates of sickness and other expenses of administration arising owing to the absence of medical benefit in Ireland.

Grants are to be made from the Special Drug Fund towards the cost of drugs where epidemics and other abnormal conditions have caused an excessive demand upon the funds available for this purpose. The Mileage Fund will provide special grants in respect of mileage in sparsely populated districts, exclusive of the Highlands and Islands of Scotland.

The Medical Service in the Highlands and Islands of Scotland.

Whilst a grant of £10,000 for mileage and other special charges to medical men in the Highlands and Islands of Scotland is included in the supplementary estimates, it is understood at Westminster that this is in no way intended by the Government to be a solution of the problem of medical service in that part of the country. It is stated unofficially that a sum of £32,000 will be included in the Scottish estimates next session to be expended on the organisation of the service. According to report the Scottish Local Government Board will have the administrative control of the money.

Inflammable Flannelette.

Mr. Theodore Taylor's Fabrics (Misdescription) Bill, which was introduced in the House of Commons on Tuesday, Feb. 4th, is designed to check the sale of inflammable flannelette which has caused so many deaths from burning. A standard of safety is set up to which fabrics sold under the description of safe must conform. The Bill has been read a first time.

Mental Deficiency Legislation.

An official denial has been given by the Prime Minister to the report that mental deficiency legislation will not be proceeded with next session.

Ireland and Medical Benefit.

The *personnel* of the Departmental Committee which has been appointed to inquire and report into the desirability of extending medical benefit to Ireland is not different from what has been expected at Westminster. It is anticipated that it will carry out its investigations with little delay, and if it reports in favour of an extension of medical benefits to Ireland legislation may be introduced by the Government in the coming session to give effect to its recommendations. The intention of the Committee is to deal first with the urban areas in Ireland, and it is announced that it will take evidence in Belfast and Dublin this month. Two or three months may elapse before the evidence as to the rural districts will be heard.

Tuberculosis Prevention (Ireland) Bill.

The Tuberculosis Prevention (Ireland) Bill has received a second reading in the House of Commons.

HOUSE OF COMMONS.

WEDNESDAY, JAN. 29TH.

Grievances regarding Medical Benefit.

MR. F. HALL (Dulwich) asked the Chancellor of the Exchequer whether, in view of the misapprehension as to the Government's [illegible] doctors by insured persons, he [illegible]

[illegible] the negative.

Independent Arrangements under the National Insurance Act.

[illegible] certain cases it had been stated must be brought when application was [illegible] provisions of Section 16 (3) of [illegible] inquiries.

MR. GWYNNE: I shall send the right honourable gentleman particulars

Allotment of Insured Persons.

[illegible] conditions under which insured persons in each area may be allotted [illegible] responsible. I am not aware which Insurance Committees have made arrangements with medical men on the panel granting such limitations.

MR. GWYNNE: Will the right honourable gentleman inquire whether any Insurance [illegible] Will he also notify Ins[illegible] way?—MR. MASTERMAN: [illegible] *notification. I have no* [illegible] subject.

Appointments under the National Insurance Act.

[illegible] to [illegible] r to [illegible] has [illegible] In [illegible] not

The Panel in the Isle of Ely.

MR. WORTHINGTON EVANS asked the Secretary to the Treasury to state (1) upon what terms Messrs. Morgan and Dimock had been [illegible] insured persons to make their own [illegible] complete responsibility for all the insured persons in these districts.

MR. WORTHINGTON EVANS: [illegible] this district? *If s*[illegible] Insurance Commis[illegible] the list system, if I [illegible] been suspended, and [illegible] has been accepted by the Commissioners.

Publication of Panel Lists.

[illegible] asked the Secretary to the Treasury [illegible] persons, he would arrange that the [illegible] Would it not be possible, without [illegible] of the additional doctors down in [illegible] MR. MASTERMAN: The list goes round to many hundreds of places, and it would be difficult to arrange that.

Numbers of Insured Persons.

Answe[illegible] The approxi[illegible] contribu[illegible] men and [illegible]

Naval Hospital Accommodation at Harwich.

[illegible] Harwich is one of those places on the East Coast which have only in recent years acquired a naval importa[illegible] treatment of [illegible] stationed the[illegible] board the pa[illegible] for sick, and [illegible] opportunities [illegible] opposite to [illegible] appointed [illegible] establishment. In ordinary times there is room in this hospital for treating such naval cases, but if there were to be an unusual amount of sickness among the boys at Shotley difficulties in providing accommodation might arise. The First Lord of the Admiralty is therefore making provision in the forthcoming Estimates for certain extensions at Shotley Hospital which will [illegible] course

Medical Inspection of School Children.

Captain CLIVE asked the Parliamentary Secretary to the Board of Edu[illegible] have [illegible] but [illegible] scho[illegible] they [illegible] whet[illegible] from [illegible] first [illegible] Boar[illegible] of g[illegible] men[illegible] elder [illegible] of g[illegible] matter.

Water supplies in Rural Kent.

MR. CHARLES BATHURST asked the Parliamentary Secretary to the Local Government Board whether his attention had been called to the [illegible] districts of Kent, [illegible] number of rural [illegible] their supply of [illegible] attention has [illegible] calities in rural [illegible] cation with the [illegible] question, I hope [illegible] sources of water-[illegible]

[illegible] the Secretary for Scotland whether it [illegible]

Housing in South Dublin Rural District.

[illegible] Board will [illegible] necessities of [illegible] into account [illegible] each district and the [illegible] district.

THURSDAY, JAN. 30TH.

Payments to Panel Practitioners.

MR. CASSEL asked the Secretary to the Treasury to state at what periods payments would be made to doctors on the panels who were remunerated on the capitation system, and when would the first payments be made; whether the lists of patients furnished by doctors would be accepted as sufficient for the purpose of payment, or whether it would be necessary to produce the patients' tickets; and whether remuneration would commence to run from Jan. 15th, 1913, or the date when the doctor accepted an insured person as his patient, and how would such date be ascertained.—Mr. Masterman replied: The Regulations contemplate quarterly payments, but, as I have previously stated, arrangements may be made by Insurance Committees whereby payments may be made on account during the quarter. The lists of patients sent in by the doctors will be checked by the Insurance Committees from the lists furnished by the societies, not from the medical tickets. The payments are due as from Jan. 15th or whatever later date the doctor joined the panel.

The Extent of Sanatorium Benefit.

In reply to a question put by Mr. Cassel asking in respect of an individual case of sanatorium benefit in London what articles the insured person was entitled to receive as part of domiciliary treatment, Mr. Masterman said that the Insurance Committee were empowered to authorise the supply of articles which were ordered by the doctor and were ancillary to the treatment, but had no legal power to supply articles not falling within this description.

Mr. Cassel: Is it to be taken as a rule when the doctor orders ancillary treatment in the case of tuberculosis that the things are not to be supplied?—Mr. Masterman: No, only the articles which can be legally supplied under the Act which rules the ancillary treatment of tuberculosis. The Act is not an Act for giving general relief to poor people.

Mr. Cassel: Is it a fact that these articles are confined to cod-liver oil and extract of malt?—Mr. Masterman: No, a cheque for a considerable sum, I think nearly £10, was paid over in this case for other articles which were for ancillary treatment, but the Insurance Committee have no power to supply coal or bread or meat.

Mr. Cassel: Is the right honourable gentleman aware that the information given by the doctor in charge of the case is that the articles he ordered were not coal, but supplementary diet, the daily visits of a nurse, and proper bedding?—Mr. Masterman: These were the articles supplied.

Mr. Cassel: Is it not the case that these articles were only supplied after such delay as to cause grave and serious injury to the patient?—Mr. Masterman: No, I have answered that already. That is not so.

Dispensing Medicines under the National Insurance Act.

Mr. Masterman (replying to Mr. O'Grady) said: No persons qualified to dispense medicines prior to the passing of the National Insurance Act have been disqualified from dispensing medicines by that Act. The Insurance Commissioners have no power to vary the conditions laid down in Section 15 (5) of the Act as to the supply of medicines to insured persons.

Mr. O'Grady: Is it not a fact that there are a large number of chemists in this country who are qualified, although they are not members of the Pharmaceutical Society, and have been in the habit of dispensing medicines for doctors for a period of years, and is it not a fact that the Act specifically relates to those men when it speaks of having to get a certificate from a doctor to dispense?—Mr. Masterman: I am not sure, but it only follows the limitation laid down in the Pharmacy Act.

Mr. O'Grady: Does that mean that the Act constitutes a monopoly for the members of the Pharmaceutical Society to the exclusion of other skilled men?—Mr. Masterman: The Pharmacy Act lays down certain qualifications for chemists, and those are embodied in the National Insurance Act.

Mr. O'Grady: Can these chemists be placed on the panel of dispensers for things not down in the schedule of poisons?—Mr. Masterman: I am not sure of that.

Mr. O'Grady asked the right honourable gentleman whether he was aware of the fact that in the east municipal ward of East Leeds there are 6463 persons on the electoral register, and that for the larger population in the locality which this number represented there was only one chemist's shop at which medicines might be dispensed under the National Insurance Act; and whether, in view of the hardship that this imposed on poor people, as well as the danger to life in having to come from the opposite end of the municipal division to obtain medicines, the unregistered but qualified chemists in business in the neighbourhood should be given the right to dispense under the Act.—Mr. Masterman said in reply: I have communicated with the Leeds Insurance Committee, and they are making inquiries as to the adequacy of the number of chemists in the district referred to. I may, however, point out that in any case it would not be possible to authorise the supply of medicines requiring dispensing to be arranged by other persons than those entitled to make these arrangements under the Act.

Mr. O'Grady asked the right honourable gentleman whether he was aware of the fact that the prescriptions made out on paper by the doctor and given to a patient to be dispensed at the store of a chemist who was on the panel as a dispenser [illegible] times contained a list of medical [illegible] this meant that the sale of th[illegible] was bound to go to such chemists to the loss of business of those chemists and drug store proprietors who could only be on the panels for the supply of medical appliances; and whether, having regard to the fact [illegible]hemist [illegible] to the [illegible] would be taken to alter this state of [illegible]d The National Insurance Act gives the insured person a free choice as to the chemists or other persons on the lists from whom he can obtain appliances; and I could not take any action which would have the effect of depriving the insured person of that choice.

Medical Inspection of Elementary School Children.

Mr. Rowntree asked the President of the Board of Education whether, as a result of the medical inspection in the elementary schools of England and Wales during recent years, it was possible to estimate the number of children attending these schools who were suffering from the following defects, and the approximate percentage of the whole which these numbers represent: defective vision, defective hearing, ear disease, adenoids and enlarged tonsils, injurious decay of teeth, unclean bodies, ringworm, tuberculosis, heart disease, and malnutrition.—Mr. J. A. Pease replied: The latest estimate is to be found in Paragraph 314 on p. 256 of the report for 1910 of the Board's chief medical officer. I cannot assert that there is as yet any improvement in the condition of the entrants into the schools, but we believe that substantial progress is being made in the case of children who have already come under inspection.

Medical Institutions and the National Insurance Act.

Mr. Duncan Millar asked the Secretary to the Treasury in how many instances existing medical institutions or associations had been approved under Section 15 (4) of the National Insurance Act; and in how many cases medical treatment was provided by the rules of such associations for dependents as well as for insured persons.—Mr. Masterman furnished the following written answer: 109 systems and institutions have been approved. With one exception the rules provide for the treatment of dependents.

District Nursing under the National Insurance Act.

In reply to Sir A. Williamson, Mr. Masterman wrote: The Insurance Commissioners have no funds from which to make any grant for the support of district nurses. Under Section 21 of the Act, an Approved Society or an Insurance Committee may subscribe for this purpose, and experience of the working of the Act is necessary to show what will be the effect of this provision.

MONDAY, FEB. 3RD.

Old Members of Friendly Societies.

Lord Ninian Crichton-Stuart asked the Secretary to the Treasury whether the Government were prepared to help, financially or otherwise, those members of Friendly Societies over 65 years of age who were insured persons, and therefore eligible for sickness benefit, to get medical benefit.—Mr. Masterman replied: Yes. The supplementary estimates laid on the table of the House on Friday include provision for a capitation grant of 2*s.* 6*d.* in respect of those insured persons whose societies elect to provide medical treatment as one of the benefits to be given under Section 49 of the Act.

In reply to Mr. Rupert Gwynne, Mr. Masterman said: The National Insurance Commissioners are preparing and will issue this week a table for the guidance of societies in determining the benefit which may be given to members of societies over 65 on July 15 last, which decide to give medical attendance and treatment for such members as one of the benefits to be given under Section 49 of the Act.

Medical Benefit in Chatteris and Wisbech.

Mr. Worthington Evans asked the Secretary to the Treasury how many insured persons lived in the districts of Chatteris and Wisbech under the jurisdiction of the Isle of Ely Insurance Committee, for whom four doctors had undertaken complete responsibility; and whether in these districts the four doctors were allowed to dispense.—Mr. Masterman answered: The number of insured persons living in the urban district of Wisbech is estimated at 3607 and in the urban district of Chatteris at 1753. The answer to the second part of the question is in the negative.

The Insurance Committee of the Isle of Ely.

Mr. Worthington Evans asked the Secretary to the Treasury whether insured persons were allowed to make their own arrangements under Section 15 (3) of the National Insurance Act by the Insurance Committee of the Isle of Ely; and what limits of time within which applications for permission to make private [illegible] made have been fixed by such committee.—M[illegible] The Isle of Ely Insurance Committee will exerc[illegible] on them by Section 15 (3) of the National Insurance Act in the same way as other Insurance Committees, except in the areas in which the panel system has been suspended. In those areas all the sums available for the medical treatment of insured persons will be paid by the Committee to the doctors who had undertaken complete responsibility for their treatment. I am not aware that any limits of time such as are referred to in the second part of the question have been fixed by the committee.

Mr. Worthington Evans asked the right honourable gentleman to state on what terms Messrs. Morgan and Dimock had been engaged as doctors for the Isle of Ely under the National Insurance Act; and whether any assurance had been given to them that the panel would be closed or not adopted for two years or any other period, and by whom such assurance was given.—Mr. Masterman said in reply: Dr. Morgan only rendered service pending the completion of the committee's arrangements for medical service in the Chatteris district. Dr. Dimock and the other doctors who have undertaken the attendance and treatment of insured patients in the Chatteris and Wisbech districts will be remunerated on the same terms as panel doctors elsewhere, and they have entered into agreement with the Local Insurance Committee to take complete responsibility for the insured persons in those districts for a period of two years, subject to three months' notice on either side.

Mr. Worthington Evans asked the right honourable gentleman to state the names of the four doctors appointed by the Isle of Ely Insurance Committee by special arrangement to undertake complete responsibility for insured persons in the districts of Chatteris and Wisbech, and whether he could state which of the four was assigned to Chatteris district, and the area of such district and of the Wisbech district, and which, if any, of these doctors had previously practised in either of these districts.—Mr. Masterman wrote in reply: The names of the four doctors in question are William Groom, M.D., Harry Groom, M.D., Horace Dimock, M.B., M.R.C.S., L.R.C.P., and P. Coffey, L.R.C.S., L.R.C.P. The three doctors whose names are first mentioned are treating insured persons in the borough of Wisbech, and Dr. Coffey is undertaking the same work in the urban district of Chatteris. Dr. William Groom and Dr. Harry Groom have both practised in the Wisbech area.

The Income Limit in Perth.

Mr. Charles Duncan asked the Secretary to the Treasury whether he was aware that the Perth Burgh Insurance Committee had fixed a £2 limit for medical benefit under the National Insurance Act on the ground that a panel of doctors could not otherwise have been set up; whether this action, which was causing dissatisfaction amongst insured persons in Perth, was in order; and what action he proposed to take in the matter.—Mr. Masterman answered: Under Section 15 (3) of the Act the question of whether an income limit above which persons must make their own arrangements for receiving medical attendance and treatment and receive a contribution towards its cost, instead of [illegible] resident in the area. I am informed that the Perth Insurance Committee had given public notice accordingly, and a meeting will be held at which representatives of societies will have an opportunity of expressing their views before a final decision is arrived at.

TUESDAY, FEB. 4TH.

Ireland and Medical Benefit.

Mr. J. REDMOND asked the Chancellor of the Exchequer whether he was [illegible] existing." [illegible]

[illegible] GEORGE: They have to consider Irish conditions, which are very different from ours. It is not for me to express an opinion as to whether the system obtaining in England shall apply to Ireland. They will have to adapt it in some way to the conditions existing there.

Rural Medical Men and the National Insurance Act

In answer to Mr. WRIGHT, Mr. MASTERMAN said: A doctor in a rural district who does his own dispensing under the conditions laid down in Sections 45 and 47 of the Medical Benefit Regulations will receive on the capitation system the total capitation sum for medical [illegible]

Sanatorium Benefit.

Replying to Mr. WHELER, Mr. MASTERMAN said: An insured person is entitled to such sanatorium benefit as the Insurance Committee recommends. The nature of the treatment is determined by the committee acting on the advice of the tuberculosis officer or other consulting medical man.

Medical Representation on Insurance Committees.

Mr. MASTERMAN, in reply to Mr. COOPER, said: The Insurance Com- [illegible] ate of [illegible] Insur- [illegible] ers of [illegible] y the [illegible] to the [illegible] nt of [illegible] have [illegible] edical [illegible]

Panel Medical Men and Professional Secrecy.

[illegible] ment which might be required for statistical purposes to be entered in the doctor's private day book.—Mr. MASTERMAN replied: The arrangements for keeping and furnishing the records by doctors secure that information that would connect the name of a patient with an entry as to a particular kind of disease, could not be obtained by the Commissioners, committee, or society. The nature of the evidence which a society accepts in support [illegible] the Act.

Milk Legislation in Scotland.

[illegible] honourable Member refers.

WEDNESDAY, FEB. 5TH.

Suggested Amendment of the Insurance Act.

Replying to Mr. GODFREY LOCKER-LAMPSON, Mr. MASTERMAN said: If and when experience shows that amendments of any details of the [illegible]

Appointments.

Success [illegible] *lic Institutions,* [illegible] *this column, are* [illegible] *ected to the Sub-* [illegible] *morning of each* [illegible]

[illegible] has been appointed Chief Tuberculosis [illegible]

Harm Diseases of the Eye. 10.30 A.M., Surgical Registrar: Demons tion of Cases in Wards. 12 noon, Mr. Souttar: Surgical Anato of the Abdomen. 2 P.M., Medical and Surgical Clinics. X R Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnou Hospital, Greenwich.

Monday.—Out-patient Demonstrations:—10 A.M. Dr. G. Hol Medical. Mr. H. Curtis: Surgical. 12 noon, Mr. G. N. Bi Throat, Nose, and Ear.——2.15 P.M., Mr. W. Turner: Surg 3 P.M., Mr. W. Turner: Operations. 3.15 P.M., Sir D Duckworth: Medicine. 4.15 P.M., Mr. R. Lake: Ear and Thr

Tuesday.—Out-patient Demonstrations:—10 A.M., Dr. C. Sin Medical. Mr. A. J. Walton: Surgical. 12 noon, Dr. MacCormac: Skin.——2 P.M., Mr. L. McGavin: Operati 2.15 P.M., Mr. R. Carling: Surgery. 3.15 P.M., Dr. G. Ran Medicine.

Wednesday.—Out-patient Demonstrations: 10 A.M., Dr. F. L mead: Medical. Mr. P. Cole: Surgical. 11 A.M., Mr. R Bickerton: Eye.——2 P.M., Mr. L. V. Cargill or Mr. Cho Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.15 P Mr. Cargill: Eye Clinique. 4.30 P.M., Mr. C. C. Cho Surgery.

Thursday.—Out-patient Demonstrations:—10 A.M., Dr. G. Hol Medical. Mr. H. Curtis: Surgical. 12 noon, Mr. G. N. Bi Throat, Nose, and Ear.——2 P.M., Mr. R. Carling or Mr. Turner: Operations. Dr. A. Davies: Pathological Demons tion. 3.15 P.M., Dr. R. Wells: Medicine.

Friday.—Out-patient Demonstrations;—10 A.M., Dr. C. Sin Medical. Mr. A. J. Walton: Surgical. 12 noon, Dr. MacCormac: Skin.——2 P.M., Mr. L. McGavin: Operati 2.15 P.M., Sir John Rose Bradford; Medicine. 3.15 P.M., L. McGavin: Surgery.

Saturday.—Out-patient Demonstrations: 10 A.M., Dr. F. Langm Medical. Mr. P. Cole: Surgical. 11 A.M., Mr. R. E. Bicker Eye.——10 A.M., Dr. W. Steuart: Radiography.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince Wales's General Hospital, Tottenham, N.

Monday.—Clinics:—10.30 A.M., Surgical Out-patient (Mr. Gillespie). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipha Nose, Throat, and Ear (Mr. H. D. Gillies). 3 P.M., Clin Pathology and Pathological Demonstration (Dr. W. H. Dunca

Tuesday.—Clinic; 2.30 P.M., Operations. Clinics:—Medical O patient (Dr. A. G. Auld); Surgical (Mr. Howell Evan Gynæcological (Dr. A. E. Giles). 3.30 P.M., Medical In-pati (Dr. A. J. Whiting). 4.30 P.M., Lecture:—Dr. A. J. Whiti Recent Investigations in the Treatment of Heart Disease (Il trated by polygraphic tracings).

Wednesday.—Clinics:—2 P.M., Throat Operations (Mr. Gilli 2.30 P.M., Children's Out-patient (Dr. T. R. Whipham); S (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 P.M., X R (Mr. W. Steuart); Clinical Pathology and Pathological Dem stration (Dr. W. H. Duncan). 5.30 P.M., Eye Operations (Brooks).

Thursday.—2.30 P.M., Gynæcological Operations (Dr. A. E. Gil Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surg (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chapp 4.30 P.M., Lecture:—Dr. C. F. Hadfield: Ethyl Chlor Anæsthesia

Friday.—2.30 P.M., Operations. Clinics:—Medical Out-pati (Dr. A. G. Auld): Surgical (Mr. E. Gillespie); Eye (Mr. R. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie); Clin Pathology and Pathological Demonstration (Dr. W. A. Dunca

LISTER INSTITUTE OF PREVENTIVE MEDICINE, Chel Bridge-road, S.W.

Tuesday.—5 P.M., Dr. G. H. K. Macalister: Various Products the Tubercle Bacillus used in Diagnosis and Treatment a Current Views upon their Mode of Action.

Thursday.—5 P.M., *Dr. J. A. Arkwright: Some* Recent Work the Agglutination of Bacteria with Special Reference *to Agg* tination with Acids.

S OF THE CHEST,

t The Diagnosis of

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City road, E C
Course of Lecture-Demonstrations on Diseases of the Chest, with Special Reference to Tuberculosis (including a Tuberculin Course) —
MONDAY —4.30 P M , Dr Ridge, 8 P M , Dr B King (Tuberculin Course)
TUESDAY —4 30 P M Dr P B Ridge (Tuberculin Course)
WEDNESDAY —4.30 P M Dr S Thompson (Tuberculin Course)
THURSDAY —4 30 P M Dr M Leslie, 8 P M , Dr B King (Tuberculin Course)
FRIDAY —4 30 P M , Dr Phear (Tuberculin Course)
SATURDAY —10 30 A M , Dr M Leslie (Tuberculin Course)

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen square, Bloomsbury, W C
TUESDAY —3 30 P M , Clinical Lecture:—Dr A Turner Sensory Conduction in the Spinal Cord
FRIDAY —3 30 P M , Clinical Lecture —Dr A Turner Sensory Types of Disseminated Sclerosis

CANCER HOSPITAL, Museum of the Hospital Fulham road, S W
WEDNESDAY —5 P M , Mr C Ryall Cancer of the Tongue (illustrated by cases and microscopic and other specimens)

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention should be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor"

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET

THE Index and Title page to Vol II of 1912 were given in THE LANCET of Dec 28th, 1912

VOLUMES AND CASES

VOLUMES for the second half of the year 1912 are now ready Bound in cloth, gilt lettered, price 16*s* , carriage extra

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2*s* , by post 2*s* 3*d*

To be obtained on application to the Manager, accompanied by remittance

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W C , are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c , should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows .—

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs 50 per month)

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied

SOLE AGENTS FOR AMERICA—MESSRS WILLIAM WOOD AND CO , 51, Fifth Avenue, New York, U S A

Y.—York County Hospital, Secretary of.

Z.—Messrs. A. and M. Zimmermann, Lond.

the current of its secretions; and secondly, Baumgartner's failure to produce experimentally a descending tuberculosis by injecting tubercle bacilli into the urethra of a rabbit. With the idea of testing the power of organisms to travel from the urethra to the testicle against the current of the secretions, and in the hope of gaining some indication of the path that they followed, I undertook a series of experiments on animals. Following on the lines of Paladino Blandini I inoculated the anterior urethra of a series of guinea-pigs with a loopful of some definite organism, and after an interval of 12 hours made a careful bacteriological examination of various portions of the genito-urinary tract. For the first four experiments B. prodigiosus was chosen as its characteristic pigment allowed of its easy recognition. A loopful was placed in the anterior urethra, and the guinea-pig killed at the end of 12 hours. In three out of the four cases an abundant growth was obtained from the epididymis, and a much scantier one from the testis. The same organisms were also found in the vesicles and in the plexus of [illegible] ns. A control cultivation of [illegible] ated with other organisms, [illegible] cases showed the presence of numerous organisms in the lymphatics surrounding the vas. In the lumen of the vas itself few or no organisms were found. The appearance was such as to suggest that the organisms reached the testicle by means of the lymphatics, and not by the lumen of the vas, as Paladino Blandini supposed.

The difficulties of tracing tubercle bacilli after they have been inoculated into the urethra are very much greater. Cultural methods are here *almost impossible, and but little* multiplication of the bacillus occurs to assist the searcher in his hunt. The examination of the tissues of the epididymis or cord is a tedious one and open to error. My own results when using tubercle bacilli were very unconvincing, for in only one out of five cases was I able to find unmistakable tubercle bacilli in the testicle after inoculation of the urethra. Paladino Blandini, on the other hand, succeeded in demonstrating tubercle bacilli in the epididymis 30 hours after urethral inoculation in every one of his ten experiments. Moreover, Delli Santi was able to recover virulent tubercle bacilli from the testicle of a dog a few hours after having injected them into the ureter. Although virulent, the bacilli had produced no tuberculous reaction in the testicle. In spite, therefore, of this failure on my part to obtain an independent and convincing proof of the accuracy of Blandini's results, I believe that what is true of pyogenic [illegible] organism of tuberculosis, and [illegible] the epididymis by descending [illegible] exus of lymphatics. My own experiments led me to believe that not only all varieties of micro-organisms, but also inanimate granules of carmine or iron are absorbed from the urethra and carried by the lymphatics to the testicle.

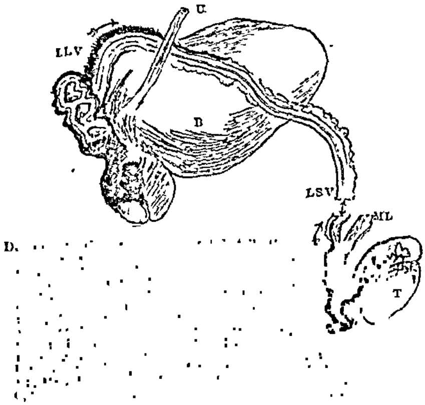
Baumgartner's failure to produce a descending tuberculosis experimentally in rabbits is, in my opinion, no proof of any inability *on* the part of the *tubercle bacillus to descend* the cord in a direction contrary to the secretions. Rather is it a demonstration of the truth of the fact that the mere presence of tubercle bacillus in a tissue is of itself not sufficient to determine a tuberculous process. In the absence of a suitable soil the bacilli are destroyed by the healthy tissues. The inoculation, then, of the urethra or even of the cord is insufficient; it is necessary also to prepare the testicle for the reception of the bacillus by previously injuring it. This is a specimen of the urino-genital system of a rabbit whose urethra I inoculated with a loopful of tubercle bacilli. The day preceding the inoculation I exposed the left testicle of the rabbit and subjected it to a certain amount of trauma. Three days after the inoculation a hydrocele appeared on the same side, and the testicle became swollen, tender, and inflamed. At the end of six weeks the rabbit had lost flesh and displayed a tuberculous urethritis, together with a *swollen, indurated epididymis* on the injured side. The post-mortem examination showed a distribution of the tuberculous lesions exactly similar to that which is usually found in the human subject. The epididymis was the seat of a well-developed tuberculosis, which had also attacked the seminal vesicle on the same side. The testicular and prostatic extremities of the cord were considerably enlarged, the intervening portion appearing but very slightly thickened. The opposite testicle was natural. Microscopic examination confirmed the above. Sections stained by the Ziehl Neilsen method showed the presence of numerous tubercle bacilli in the epididymis and their absence in the body of the testis. Although the experiment supplied a valuable corroboration to the theory of a descending tuberculosis, it failed in one very important respect. The discovery of four or five miliary tubercles on the peritoneum showed that the tuberculosis was on the point of becoming generalised, and that the necropsy had been performed too late to eliminate the possibility of infection of the testicle through the blood stream. However, the advanced stage reached by the tuberculous epididymitis compared with the meagre and youthful signs of generalisa*tion renders this improbable.*

The Distribution of the Tuberculous Tissues.

The possibility of the lymphatics of the cord acting as the path along which a descending infection of the testicle may advance is supported to some extent by the appearance of specimens obtained from the post-mortem room.

Fig. 2 is a typical example of the condition of the cord that is found in a case of genital tuberculosis. The prostatic and the testicular extremities of the cord are markedly affected, whilst the intervening portion appears healthy. If transverse sections be made and examined microscopically the following is found to be the exact distribution of the tuberculous lesions. Transverse sections of the prostatic extremity show that the vas itself is comparatively healthy, but that it is surrounded by a thick shell of tuberculous tissue, due to infiltration of the lymphatics. As the testis is approached this lymphatic infiltration gradually ceases. A section of the distal end of the vas near its termination in the epididymis shows a converse condition. Here the disease has affected the mucosa of the vas, whereas the surrounding lymphatics give little or no evidence of any lesion. The condition of affairs is represented in the diagram (*Fig. 2*), the *tuberculous lesions* being darkly shaded. This distribution suggests that the disease is disseminated from the prostate by the lymphatics, and that having encountered in the epididymis a suitable soil in which to flourish, it produces a returning wave of infection in the vas, through the agency of the secretions. It is interesting to note that the microscopic examination of the [illegible] experimentally produced in the rabbit by [illegible] stribution. [illegible] nal vesicle [illegible] of tuberculous infiltration, the inner coat of the vas being healthy. At the distal end of the vas the parts most affected were not the outer *coats* and *the lymphatics* but the innermost coats. The further the distance from the epididymis, the

FIG. 2.



more completely were the inflammatory changes restricted to the mucosa.

Apart, therefore, from other considerations, the distribution of the tuberculous tissues alone suggests the existence in these cases of two opposing waves of infection, a centrifugal and primary one, travelling from the prostate along the lymphatics; a centripetal and secondary one, in the lumen of the vas, due to the flow of infected secretions from the diseased epididymis.

Summary.

From a consideration of the above it would appear that infection of the testicle takes place in tuberculosis, as in gonorrhœa, by means of the cord and not by the blood stream. That cases of hæmatogenous infection occur cannot be denied, but they are few in number. The evidence in favour of the frequent occurrence of a descending genital tuberculosis may be tabulated as follows:—

Clinical evidence.—1. It is extremely rare to find tubercle of the epididymis without discovering some indication of disease of the prostate or the vesicles. 2. Prostatic tubercle is not infrequently found without any lesion of the testicle. 3. The appearance of a tuberculous epididymitis is often preceded by symptoms of prostatitis or vesiculitis—the so-called prodromata of tuberculous epididymitis. 4. The earliest signs of tuberculous disease are found at the lower pole of the epididymis. This is the first position which opposes the line of march of the invading organisms. 5. Tuberculous disease of the testicle is analogous to acute infections which are known to have been produced by extension from the urethra. The ordinary type of tuberculous epididymitis has no analogy to the hæmatogenous orchitis of mumps.

Pathological evidence.—1. Lesions of the testicle without disease of the prostate are rare, whereas tuberculous lesions of the prostate are not infrequently found unaccompanied by disease of the testicle. 2. When tubercle of the testicle is found in association with tubercle of the prostate, the lesions in the prostate generally have the appearance of being older than the lesions in the epididymis. 3. Tuberculous nodules in the lower pole of the epididymis usually appear older than those in the upper pole. They are the first to soften and break down.

Experimental evidence.—1. Micro-organisms and inanimate granules are rapidly absorbed from the urethra and carried to the testicle. 2 A tuberculous epididymitis may be experimentally obtained by inoculating the urethra after having damaged one of the testicles.

THE ETIOLOGY OF TUBERCULOSIS OF THE PROSTATE.

As a result of the foregoing conclusions it would seem that the prostate, with its surrounding network of lymphatics, plays an extremely important rôle in the development of tuberculosis of the testicle. It is the gateway to tuberculous infections of the testicle, just as it is the gateway to gonococcal and pyogenic infections. If this is so, one would expect to find that tuberculous lesions of the prostate are extremely common. Post-mortem statistics show that such is the case, and that in chronic urino-genital tuberculosis the prostate is the organ which least frequently escapes.

On what does this frequent affection of the prostate depend, and what are the paths by which it is infected? In the case of the prostate four possibilities present themselves for consideration: (1) Infection by the blood stream; (2) extension of the disease by continuity of structure; (3) direct infection per urethram; and (4) infection through the agency of the urine.

It is probable that examples of all of these modes of infection are to be met with. A primary tuberculous prostatitis due to infection by the blood undoubtedly occurs. So also does tubercle of the prostate due to an extension from neighbouring structures, such as the bladder or the peritoneum. Less common and less certain is direct infection by the urethra. Still, the possibility of infection after coitus must be considered. Deville undertook an investigation of the vaginal discharges in genital tuberculosis amongst women. In four out of the eight cases examined he was able to demonstrate tubercle bacilli in the discharges. On examining the husbands of these cases he found that all were suffering from tuberculous epididymitis. Infection per urethram during coitus is therefore probable, although it is certain that infection of the female by the male is more frequent than infection of the male by the female.

Infection of the Prostate by the Urine.

It is, however, upon the importance of the urine as a vehicle of infection that I wish to lay especial emphasis.

The urine is, in the lecturer's opinion, a far more frequent agent of infection to the prostate than is the blood. The presence of a small tuberculous focus in the upper portion of the arbor urinæ is sufficient to ensure the presence of tubercle bacilli in the urine and the possibility of prostatic infection by this agency. A very large number of cases of tuberculosis of the prostate are secondary to lesions in one of the kidneys. Sometimes the prostate is infected and the bladder escapes.

Anatomical considerations render the prostate particularly liable to infection from any infective agent that may be carried to it by the urine. A medial section through the body shows that the bladder and prostate together form an excellent segregating apparatus. Any deposit in the urine would naturally tend to collect in the lowermost part, formed in the upright position by the prostate. Infective material may consequently be brought into contact with the prostatic urethra for a considerable length of time. Given any condition of lowered resistance in the tissues, such, for example, as a previous inflammation, the chance of infection would be great. Moreover, in the prostatic urethra are natural crypts and ducts in which tubercle bacilli may easily become lodged, and thus escape the fate of being swept down the urethra during the act of micturition.

Having seen, therefore, that the prostate is particularly susceptible to urine infection, it remains only to discuss the conditions under which tubercle bacilli are found in the urine.

Bacilluria due to a Tuberculous Focus in the Kidney.

The presence of tubercle bacilli in the urine secreted by one of the kidneys is generally an indication of renal tuberculosis. In a very large number of cases of tuberculous disease of the prostate a primary focus exists in one of the two kidneys, and is the *fons et origo* both of the bacilluria and of the prostatic trouble. In some cases the primary lesion in the kidneys may be so insignificant that it is impossible to detect it by clinical means. Post-mortem statistics show the frequency with which tuberculosis of the lower urinary passages is associated with an undiagnosed focus in the kidney. Nor are these cases always revealed by a post-mortem examination. It is only after a careful microscopic examination of the kidneys that we can with any certainty state that they are free from suspicion. The microscope will occasionally reveal a tuberculous nodule in what appeared to the naked eye a perfectly healthy organ.

Yet in spite of this a certain number of cases of prostatic and vesical tubercle occur in which a careful investigation of the kidney fails to discover the changes that are commonly regarded as characteristic of tuberculous processes. By what means, in such cases, may tubercle bacilli gain an entry into the urine? This question of the infection of the prostate by the urine in the absence of any renal tuberculosis requires careful consideration.

Infection by the Urine in the Absence of a Typical Renal Tuberculosis.

The question of the elimination of bacteria by the healthy kidney has provoked much discussion. Bield, Krauss, and Pawlowsky held, and attempted to prove experimentally, that this excretory action exists The investigations of Wysskovitch, Spelz, Carl, and in particular those of Metier, have shown, however, that in all probability healthy renal tissue is impermeable to organisms. In the face of this and of other experimental evidence any theory which presupposes the secretion of tubercle bacilli by the healthy kidney must be abandoned. If tubercle bacilli are demonstrated in the urine coming from a kidney it may be assumed that that kidney is in an *unhealthy* condition. There are two facts, however, in connexion with this that are of the utmost importance. Firstly, it must be remembered that the amount of damage which a kidney must undergo in order to render it permeable to organisms is extremely slight. Secondly, it must be borne in mind that a great many varieties of atypical tuberculosis of the kidney undoubtedly occur, so that a kidney which at first sight may appear to be free of tuberculosis may actually be acting as a focus from which tubercle bacilli are constantly passing into the urine The subject, therefore, of the rôle played by the kidney as a factor in tuberculous infections of the lower portions of the urino genital tract is one which requires very careful consideration

It will be necessary to investigate the pathology of atypical tuberculosis of the kidney, and to define the relationship which exists between an atypical renal tuberculosis and tuberculous lesions occurring elsewhere in the body If it should be found, for example, that phthisis is commonly associated with an unhealthy condition of the kidney we shall have at the same time established the probability that infection through the urine is frequent in such cases, for the existence of an unhealthy kidney is the prime factor *in the production of a* bacilluria

The first question therefore that demands attention is the following

Is a damaged condition of the kidney commoner in tuberculous than in non tuberculous patients?

The question is best answered by an examination of post-mortem records Le Noir has published the results of a series of necropsies upon phthisical subjects He states that *some form of nephritis was found in 50 per cent of such* cases, and that the frequency of association increased with the age and with the state of advancement of the pulmonary disease The renal lesions were both macroscopically and microscopically *unlike those of tubercle Sometimes the* kidneys resembled the kidneys of a *chronic interstitial* nephritis, and were small and fibrous In other cases the kidney appeared enlarged, and the disease involved the *epithelial elements In yet a third variety, according to* Salomon, microscopic examination revealed a diffuse epithelioid proliferation, accompanied by an infiltration of leucocytes Other conditions are described So varied are these that Tilden Brown has recognised seven different types of kidney lesion which may be found in association with phthisis

It is still a little uncertain whether these lesions are due to the *action of toxins or to the direct action* of *the tubercle* bacillus itself Leon, Bernard, and Salomon claim to have experimentally produced similar lesions by the injection of ethereal extracts of tubercle bacilli Tournet, however, has demonstrated *tubercle bacilli in the tubules of the diseased* kidneys, and considers the lesion to be an atypical tuberculosis Rebathe and Calliardin have also drawn attention to these anomalous forms of tuberculosis and describe cases of *nephritis* which, *clinically* as well as *pathologically*, presented the picture of an ordinary chronic nephritis and yet were shown to be tuberculous Keersmaecker has gone so far as to assert that the presence of the bacillus of Koch must always be suspected in a case of chronic inflammation that evolves towards sclerosis and is of doubtful etiology All agree that *an abnormal condition of the kidneys* is extremely common in tuberculous subjects and it is the existence of this abnormal condition rather than its etiology that is of importance in the present discussion The importance lies in the fact that *whenever there exists a tuberculous focus in the body there also exists the probability of an abnormal permeability of the kidney, and the occurrence of bacilluria*

The foregoing conclusion has been arrived at from data of a pathological nature It receives support however, from independent observations derived from a clinical source Foulerton and Hillier carried out a careful examination of the urine of patients dying from phthisis In a series of cases which afterwards came to the post-mortem table tubercle bacilli were found in the urine six times In five of these albumin was found as well as tubercle bacilli At the necropsy no trace of tuberculosis of the urinary tract could be discovered From these observations two important deductions may be made firstly, that there would appear to be some connexion between the presence in the urine of albumin and the presence of tubercle bacilli, and, secondly, that in phthisical cases tubercle bacilli are excreted in the urine The common factor that determines the bacilluria and the albuminuria is clearly the abnormal permeability of the kidneys

By a process of reasoning based on clinical evidence we have arrived at the same conclusion at which we had arrived *from pathological data We have discovered that even in the absence of any typical renal tuberculosis the urine may still* be the agent by which infection reaches the prostate We have also gained an insight into the significance of albuminuria in a patient suffering from tuberculosis in any part of the body

The Significance of Albuminuria in Cases of Urino genital Tuberculosis

The routine examination of the urine in cases of genital *tuberculosis has* convinced me that in a great number of cases of genital tuberculosis a slight degree of albuminuria exists In several of my cases this abnormal permeability of the kidney was found to have been a precursor of the development of the genital tuberculosis In two patients that have been *under my observation the albuminuria* preceded the tuberculous lesions by five years Insufficient as my observations have been, they would induce me to look upon any phthisical patient with albuminuria as a person fully equipped for the development of genital tuberculosis The appearance of a nodule in the epididymis or the prostate would seem a very natural sequel to such a condition, and would direct my attention to the urine as the vehicle of infection rather than to the blood

Hitherto our attention has been centred upon descending infections In the first part of the lecture it has been pointed out that the prostate plays an important part in the localisation and in the spread of tuberculosis to the epididymis Subsequently we have discussed the paths by which tubercle bacilli may reach the prostate Emphasis has been laid upon the urine as a vehicle of infection, and it has been shown how it may act as such even in the absence of any tuberculous lesion of the kidney It now remains only to discuss the question of ascending infections spreading from the prostate or the bladder to the kidneys

ASCENDING INFECTIONS

In spite of the frequency of bilateral renal tuberculosis, the possibility of a tuberculosis that ascends from the prostate or bladder to the kidney against the urinary current has at various times been questioned It has been held by some that *in* bilateral cases the *path* of infection for both kidneys is the blood stream the conditions that favoured the development of tuberculosis in one kidney playing a similar role in the case of the second kidney *In 1892 Professor Albarran* published the results of his experimental investigations upon the subject He asserted that an ascending tuberculous infection of the kidneys is only possible if there be an accompanying retention and that organisms are unable to ascend the ureters in the face of an opposing current of urine The experiments of Hamen and Wildbolz appeared to confirm the above conclusions, and laid equal stress on the part played by retention in the production of all ascending infections

The importance of these experimental results in the elucidation of clinical problems is *supreme The acceptance* of the maxim that some degree of retention is a *sine qua non* of ascending infections would considerably reduce the probability of the spread of tuberculosis from the bladder to the kidney Pyogenic infections of the urinary tract are with great frequency accompanied by some degree of retention *but in the* case of tuberculosis obstruction of the urinary flow is exceptional The number of cases of tuberculosis of the bladder or prostate in which there is mechanical interference with the passage of urine is small, and if a stagnant column of urine in the ureter is necessary in order that the tubercle may spread upwards to the kidney this mode of infection must [illegible] infrequent That infective agents in the [illegible] y ascending the lumen of the [illegible] n Mr C T Bond's experiments upon a case of urinary fistula By injecting indigo granules into the bladder of his patient and afterwards recovering them from the fistulous *opening* in the lumbar region he was able to demonstrate the existence of an ascending mucus current in the ureter

Experimental Evidence

With a view to obtaining further information on the subject of ascending urinary *infections* in general, and the path by which organisms from the bladder may reach the kidney, the lecturer undertook a series of inoculation experiments on animals The experiments were of the same nature as *those previously made* by Professor Paladino Blandini *By their means* I was able to satisfy myself that organisms from the urethra can actually reach the kidney without the existence of any obstruction of the urinary flow. Further, I was enabled to gain some indication of the path along which they travelled.

The experiments consisted in inoculating the anterior urethra of a series of guinea-pigs with an easily recognisable organism like bacillus prodigiosus, and of afterwards hunting for the organisms in different portions of the arbor urinæ. The animal was killed usually at the end of 12 hours, and cultivations were taken from various parts of the urinary tract. The bacteriological examination of the tissues was done with extreme precautions in order to exclude the possibility of infection during the post-mortem. The results obtained were striking in the extreme. In every case I succeeded in obtaining an abundant growth of organisms from the upper extremity of the ureter at the end of 12 hours. The possibility of a blood infection was guarded against by blood cultures that in every case proved sterile. The urine was also found to be sterile. The results of the experiments are given below :—

Guinea-pig A.—Anterior urethra inoculated with B. prodigiosus Killed in 12 hours after inoculation. Heart's blood: Sterile. Urine: Sterile. Cultures from upper end of ureter: Abundant growth. Cultures from kidney (stripped of capsule): Sterile.

Guinea-pig B.—Anterior urethra inoculated with B. prodigiosus. Killed 13 hours after inoculation. Heart's blood: Sterile. Urine: Sterile. Upper end of ureter: Growth. Kidney (stripped of capsule): Sterile.

Guinea-pig C.—Urethra inoculated with B. prodigiosus. Killed after 13 hours. Heart's blood: Sterile. Urine: Sterile. Upper end of ureter: Growth. Kidney (stripped of capsule): Sterile.

Guinea-pig D.—Urethra inoculated with B. prodigiosus. Killed after 14 hours. Heart's blood: Sterile. Urine: Sterile. Upper end of ureter: Growth. Kidney (stripped of capsule). Sterile.

The results of the four experiments were absolutely consistent. In every case organisms were obtained 12 hours after urethral inoculation from the upper extremities of the ureters, but not from the kidney itself. The urine and heart's blood were always sterile. The next step in the investigation lay in discovering the path along which the organisms travelled in their journey from the urethra to the upper end of the ureter.

Path taken by Organisms from Urethra to Upper End of Ureter.

An attempt was made to answer the question by substituting organic particles for living organisms, and inoculating the urethra with carmine granules or with finely powdered ferrous carbonate. Numerous sections of the tissues were afterwards prepared and searched for particles. In the case of the ferrous carbonate the sections were treated with ferrocyanide and hydrochloric acid in order to render the iron visible. The results of these experiments were such as to favour the idea that the particles travelled to the upper extremity of the ureter by way of the surrounding plexus of lymphatics. Moreover, an unexpected and suggestive disposition of granules was discovered in the kidneys. Although no trace of iron could be found in the substance of the kidney unmistakable granules were seen lying in the capsule.

To throw further light on the idea that organisms travelled, not by the lumen of the ureter, but in the plexus of lymphatics that surrounds that channel, further experiments were undertaken. The ureter of a guinea-pig was exposed on one side, close to the bladder, and was ligatured after careful separation from its surrounding lymphatics. The anterior urethra was then inoculated in the usual way, and the animal killed at the end of 12 hours. It was found that ligature of the ureter without interference with the surrounding lymphatics had not prevented the organisms from reaching the upper end of the ureter. Moreover, a hint was taken from the results of the experiments with iron granules, and in testing the kidney for organisms it was removed enclosed in its capsule. In the previous experiments the kidney had always been stripped of its capsule before bacteriological examination. As a result of this modification a positive result was obtained. Growths were obtained from both kidneys, although the colonies were slightly less numerous on the ligatured side.

Owing to the difficulty of recognising B. prodigiosus in sections of the tissues, it was decided to repeat the experiment with organisms which were Gram-positive and therefore more easily stained. Accordingly the urethra of a guinea-pig was inoculated with three or four loopfuls of a mixture of staphylococcus aureus and of a diphtheroid bacillus. The animal was killed 13 hours afterwards, and transverse sections of the ureters and the surrounding lymphatics were prepared. The sections showed that the lymphatics outside the ureter were crowded with Gram-positive cocci and bacilli. There could be no doubt about the identity of the organisms and those previously placed in the urethra. No organisms could be seen in the lumen or walls of the ureter itself.

Specially interesting were the results obtained from a microscopic examination of the kidney. Radial sections were cut and stained for organisms. A large number of Gram-positive cocci and bacilli were found in the lymphatics of the capsule. Very few organisms were found in the substance of the kidney, and it was obvious that the few that were discovered in this situation had made their way hither by travelling along the planes of connective tissue which ran into the parenchyma of the kidney from the capsule.

The first situation, therefore, in the kidney in which organisms appear in ascending infection is the capsule. In order to confirm these unexpected results obtained from experimental inoculation I have examined bacteriologically the ureters and kidneys from cases of ascending nephritis. A proof of the correctness of the above deductions was obtained. In the ureter itself few organisms could be seen, but the surrounding lymphatics were generally found to be crowded with bacteria. The same distribution of organisms was found to exist in the kidney. Moreover, in cases of very early infection of the kidney a marked round-celled infiltration was found just subjacent to the fibrous capsule. From there invading lines of infiltration were seen running along the fibrous planes into the substance of the kidney. The distribution of organisms and the appearance of the round-celled infiltration both suggested that in, at any rate, some cases of ascending infection the organisms reach the kidney, not by the lumen of the ureter and the pelvis, but by the peri-ureteral lymphatics and the capsule. In such cases the pelvis would merely be secondarily implicated during the excretion of organisms into the urine.

The difficulties of tracing the path taken by a loopful of tubercle bacilli placed in the urethra are incomparably greater than those experienced in dealing with B. prodigiosus or pyogenic organisms. Cultural methods are impossible, and the investigation resolves itself into a laborious search for tubercle bacilli in the tissues. In spite of these difficulties Paladino Blandini obtained positive results in all of his ten experiments, proving that tubercle bacilli, like other organisms, are carried in a few hours from the urethra to the kidneys. My own results are less conclusive than the foregoing, for in only one out of five guinea-pigs inoculated have I been able to demonstrate undoubted tubercle bacilli lying in the lymphatics surrounding the upper portion of the ureter. Yet, in spite of the inconclusive nature of these results, there still remains a mass of evidence to indicate that an ascending tuberculosis may occur in the absence of urinary retention, and that the connecting link in such cases is the plexus of lymphatics surrounding the ureter. If inorganic particles and pyogenic organisms are carried by the lymphatic stream to the upper reaches of the ureter and the capsule of the kidney, it would be illogical to doubt that the same is true of tubercle bacilli.

There has ever existed a tendency to draw distinctions between pyogenic infections and tuberculous infections that do not exist. As has already been shown, tuberculous infections of the testicle are entirely comparable to pyogenic infections, and the path taken by the infective agent is probably the same in both cases. So, in the lecturer's humble opinion, may it be with ascending infections of the kidney. The characteristics which the tubercle bacillus exhibits are not fundamentally different from those of other bacilli. What is true of pyogenic infections is in the main true of tuberculous infections, and we shall not be incurring risks if we assume that the path of infection is essentially the same in the two cases.

The subject of the paths of infection in urino-genital tuberculosis is too vast to confine within the limits of a single lecture. All that I have attempted to do has been to emphasise a few points that appear to me to have escaped due recognition, and to offer a solution to some of the difficulties that have gathered round the subject.

Note.—Various diagrams were used at the lecture which it has not been found necessary to reproduce.

APPENDICITIS: A PLEA FOR IMMEDIATE OPERATION.[1]

By EDMUND OWEN, F.R.C.S. Eng.,
SURGEON TO THE FRENCH HOSPITAL, LONDON.

If we look around the circle of our personal friends and acquaintances, say of the last 20 years, we can scarcely fail to realise the fact that several have dropped out as the result of blood-poisoning started by disease of the appendix; certainly several colleagues and friends of my own have thus needlessly perished. Indeed, medical men, who, in my opinion, ought to enjoy an exemption from all disease, have paid a heavy toll to appendicitis. Not a few have been rescued by prompt operation, but too many have not accepted for themselves that definite line of treatment which, in like circumstances, they would unhesitatingly recommend to those for whose health they were responsible. But, unfortunately, medical men make, as a rule, bad patients—bad in this sense, that they do not readily hand themselves over, bodily and entirely, to their *confrères*, and bad also in that the *confrère*, when he has undertaken entire charge, is apt to hesitate to insist upon an extreme measure lest his views should fail to meet with full acceptance of his medical friend. The adjective which I have applied to some such deaths as "unnecessary" would not so readily be applied to a death from typhoid fever, cancer of the liver, or pneumonia, for instance, but it was *unnecessary* in that if only an early operation had been resorted to no calamity would have taken place. In Surgery, as in affairs of the State, what is to be desired is the greatest good for the greatest number; and if we could have back amongst us those friends whom uncontrolled appendicular disease has taken away, and could start treatment afresh, and begin it by early removal of the inflamed appendix, many of them no doubt would still be with us. But, unfortunately, the nature of our work is such that we cannot have our failures back and try them over again in a different manner. The barrister who is not satisfied with the result which his conduct of a case has received from any particular Judge, can take the case up to another Court and have it tried over again, altering his treatment, may be, and securing, perhaps, a different verdict. But there is no Court of Appeal to the surgeon who has been unsuccessful in his management of a case. It behoves him, therefore, so to act that he may take no needless risk when entering into a contest with his great Adversary, the Man with the Scythe.

Appendicitis is different from most other acute diseases in this, that one cannot tell exactly what is the state of affairs without making an incision. The senses are prevented in their working in that the deeply lying appendix is unapproachable. In the case of pneumonia, bronchitis, or heart disease, the ear tells precisely what is wrong and how things are going; when the liver, the kidney or the bladder is in trouble the sense of touch imparts valuable or precise information, whilst in most cases the eye gives important help. But an inflamed appendix can no more be felt than seen, and it is impossible to inform oneself of its exact condition. Holmes, the poet and physiologist, suggestively remarked that one cannot tell what wood a table is made of until he lifts up the cloth. And so it is with the disease in question, one cannot tell the exact state of the appendix until it has been exposed to view by operation.

I should think that no part of the body has caused so many surgical surprises as the appendix. In one case the symptoms of disease have been uncertain, or definite but slight; and when the surgeon exposes the appendix he finds it mortified. In another case he thinks that he can distinctly feel it in the iliac fossa; but in the operation not only is it absent from its proper situation, but, after half an hour's anxious search, he finds it in the depths of the pelvis, or tucked up behind the liver.

In other cases where the symptoms have been unmistakable and even acute, much to his surprise, the surgeon finds nothing worse than a little catarrhal inflammation in the vermiform process. But the commonest surprise of all is the discovery of a perforated appendix when the symptoms have been slight, and the operation has, by good fortune, been undertaken early.

The Quiet Stage.

It is generally considered that operations done on about the fifth or sixth day of the disease have a particularly high mortality. The explanation is simple: precious time has been lost. It does not mean that the surgeon is not to operate on the fifth or sixth, or any other day: it means that the disease has gone on developing from, perhaps, an apparently simple beginning; that by this time, as likely as not, an abscess has formed, and that the surgeon's chance is by so much the worse. Further, it does not mean that if the operation is postponed to the seventh, or eighth, or to any other day, the chances of recovery would be better. With, or without operation, the patient may die; but the surgeon must do his best without regard to omens or statistics. It is out of the question now that he could advise waiting for the on-coming of the "quiet stage" before operating. The quiet stage in such a case may be nothing less than the silence of death itself. There would be no "fifth" or "sixth" or any other ominous day in the course of an appendicitis if operation had been promptly resorted to. And, as for the so-called "quiet" stage, I think it a misfortune that the specious term has ever been applied to appendicitis. But it has a great attraction, and even in medical conversation it is often spoken of as if there were actually a period in the course of the disease in which all urgent symptoms, local and general, passed away, and Nature seemed to be pausing in order that the surgeon might have a free and unhampered chance of putting a happy end to the trouble. Of course, in many cases of appendicitis the urgent symptoms do so clear up; but who is to know whether in any individual case they are going to subside or to rush forward with hurricane speed? No one can possibly tell.

Associated with the theory of a "quiet stage" in the general run of cases of appendicitis is that of a "walling off" of the area of disease. In some cases there is, no doubt, a walling off, and it is pleasant when operating on them to find the appendix shut off and lying handy in a small abscess. But in hurricane cases there can be no attempt at a walling off. Nature seems to be taken by surprise, and robbed of all chance of building up protective earth-works. One could scarcely expect a gangrenous appendix to glue itself to neighbouring coils of bowel, or to cause the production of helpful plastic lymph. In these furious cases there is usually no attempt at "walling off," so the germ-laden, sero-purulent exudation may be found tracking across to the opposite side, or draining down into the pelvis. There is evidently no more chance for a "walling off" than for the on-coming of the "quiet stage."

A Fool's Paradise Stage in Appendicitis.

There is apt to be a fool's paradise stage in appendicitis, and it may come early or late in the course of the disease. Its occurrence is somewhat in this manner:—A patient has been complaining of pains in the abdomen for a day or two, with some slight tenderness in the right iliac fossa; the pulse has been, perhaps, at about 100 to 120, and the temperature at 101° F. After a baddish night the man wakes up and finds that the pains have gone, and that he is better in every way. The pulse has dropped, may be, to 90; the temperature is a degree lower, and the man's appearance is much better. His nearest relation, who has been in to see him, is delighted with his improvement. The nurse also recognises a great change, and the family doctor admits that since his visit of the previous night a marked alteration has taken place. But in spite of all this, the lower part of [illegible] ill a resistance in [illegible] some tenderness [illegible] ins. The patient is not actually better: he is worse. The state of his pulse [illegible] is of no real clinical value—it is, on [illegible] and the sensations and [illegible] o be taken as indications [illegible] persistent rigidity of the lower part of the abdominal wall.

What exactly has happened to produce this sudden change one cannot say. As likely as not, the swollen appendix has given way to internal pressure, and some thick muco-purulent fluid, or even a solid concretion, has escaped. Or and on the diagnosis being confirmed, I shall beg him *at once* to operate. And if these principles were adopted in all cases of appendicitis, the mortality of the disease would probably be lowered by 90 *per cent.*

---

[1] An abstract of a paper read before the Medical Society of London on Feb. 10th, to open a debate upon the Early Operation for Appendicitis.

Misleading Symptoms.

Whether all the views advocated in this paper prove acceptable or not, there is, at any rate, one point which ought to receive a more general recognition; it is the reference to the fact that there may be a comparative absence of clinical signs in the presence of advanced and perilous disease in the appendix. It does not at present seem to be generally realised that the pulse and temperature of a person may be normal in spite of the appendix being gangrenous or perforated; that in some of these stealthy and rapid cases there is absolutely no fullness in the fossa; and that if the chief pathological change in the appendix is gangrene there need be very little local tenderness—for there is no sensation in dead tissue; that as there is no sensation in a mortified appendix, there need be no reflex rigidity of the abdominal muscles covering the fossa; that there being no excitement of pulse or temperature, and little or no local pain or tenderness, the patient may make light of his trouble and that his aspect may be deceivingly cheerful. Thus, in the most dangerous class of cases of appendicitis there may be but little either to cause anxiety or to attract serious attention. Every operating surgeon will bear one out in this, and will agree that, for the happiness of all concerned, the family doctor should never sit pondering over his case of suspected appendicitis, but should *at once* call in surgical aid. If the surgeon then says that because he is not sure he would rather wait a little, at any rate, whatever happens the doctor will not afterwards have anything to reproach himself with. But I do not think that there are many surgeons who would counsel delay: we have all seen enough of the danger of waiting.

In no respect, I think, has improvement in surgical treatment in the last quarter of a century been more marked than in that of strangulated hernia. Taxis and the hot-bath happily have become things of the past. The general practitioner sends his patient into the hospital without hesitation or delay, or calls in the surgeon for immediate operation; and instead of there being now a high death-rate from strangulated hernia, statistics would show a most remarkable improvement. And what, in my opinion, is wanted at the present time is a similar waking up of the Profession with regard to the treatment of appendicitis. We have heard of the sailor who, when his ship was in action, saw an unexploded shell, with a time-fuse attached, land upon the deck. He did not wait to see the development of events, but taking the shell up in his arms, dropped it over the ship's side out of harm's way. An inflamed appendix is a shell with a lighted time-fuse, and though in any case it may happily fail to explode, it is far safer to lift it out at once and drop it over-board.

In the course of this paper scarcely a word has been said as regards alternative methods of treatment, for, in my opinion, *there is no place for the discussion of general measures until after the inflamed appendix is out.*

Whilst waiting for leave to operate, nothing whatever should be given by the mouth, and no fomentation or water-dressing should be used, because wetting the skin spoils the antiseptic effect of the tincture of iodine, which should at once be freely and widely painted over the region in preparation for operation. But there will be plenty of scope for treatment after the appendix has been removed, and especially so in those cases in which the blood or the peritoneum has already been poisoned by absorption.

The discussion at the present time should be directed towards the solution of the important question as to whether immediate operation or temporising ought to be the rule in the treatment of appendicitis. If the answer is unmistakably in favour of immediate operation, such subjects as that of the choice of anæsthetic, the routine washing out of the stomach before the patient leaves the table, the administration of opium or of purgatives may well be referred to; but the main question should first be settled. And in a meeting such as this the answer will be likely to prove useful in the drawing up of a Rule for the guidance of the practitioner in the treatment of every case of appendicitis.

THE REMOTE RESULTS OF TONSILLOTOMY AND TONSILLECTOMY:

AN ANALYTICAL SCRUTINY OF 220 UNSELECTED CASES.

By HAROLD WHALE, M.D. CANTAB., F.R.C.S. ENG.,
ASSISTANT SURGEON, METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL.

THE constantly recurring discussions as to the relative merits of these operations have usually centred around technique; or, when the claims of one or the other have been urged in reference to the results obtained, these claims are unsupported by systematic records of cases. Since we do not even yet know whether the tonsil is a friend or enemy, such a record is called for.

Method of investigation.—All the patients have been operated on in Mr. W. D. Harmer's clinic at St. Bartholomew's Hospital. There were 110 cases of tonsillotomy and 110 of tonsillectomy. The sexes were about equally divided; the ages at operation ranged from 3 to 43. The earliest of these operations occurred in 1908, the latest in 1912; 70 per cent. of the patients were examined at an average period of two years after operation, and all of them since May, 1912. Case-cards were made recording in detail their complaints before and after the operation, the conditions found at subsequent examination, and the results of all previous operations. From these cards were prepared a long list of classified complaints and morbid conditions, which again were cross-classified and analysed. The statistics so obtained are not given *in extenso*, excepting where they justify obvious inferences; apart from this, only the evident results of the analyses are stated.

The complaint.—In the case of certain complaints, in spite of a detailed analysis, no strong inference can be drawn as to what is the operation of choice. Thus, for obstructive dyspnœa tonsillectomy is slightly more likely to cure, and much more likely to prevent recurrence. For aural troubles (deafness, Eustachian obstruction with retracted drums, Eustachian catarrh) tonsillectomy is better. For dysphagia and for nasal affections (snoring, rhinorrhœa, epistaxis) no deduction is warranted as to the operation of choice. For gastro-intestinal troubles, remote affections such as various forms of goitre, and systemic infections (rheumatism, chorea, anæmia, tuberculosis) no strong inference is justified. It is noteworthy that in some cases rheumatism occurred after enucleation in patients who had never suffered before. The following figures show that if rheumatism and chorea be classed together tonsillectomy has a slight advantage. Rheumatism or chorea: Tonsillotomy, cured, 63 per cent.; not cured, 37 per cent. Tonsillectomy, cured, 68 per cent.; not cured, 32 per cent. Tonsillitis, voice troubles, and lymphadenitis will be discussed at more length below.

Complaints which have arisen since (the last) operation, which were unknown prior to that operation, and which might reasonably be traced to the operation.—These include tonsillitis (after tonsillotomy only), rhinitis, lymphadenitis, rheumatism and chorea, and laryngitis or functional voice troubles. In some cases deformities of the palate, &c., were responsible. To these statistical reference is made below under "Deformity," and after eliminating these it is found that, with the single exception of voice troubles, the figures obtained from the lists of complaints arising *de novo* after operation favour tonsillectomy in every case. The fact that voice troubles stand alone in that they are just as likely to be initiated by tonsillectomy as by tonsillotomy is interesting in view of what is further stated below under "Voice troubles."

Tonsillitis.—After a complete tonsillectomy faucial tonsillitis is, of course, impossible. And none of the patients who had undergone this operation even alleged that they had suffered from tonsillitis for the first time since operation—which, however, actually occurred in 3 per cent. of the tonsillotomy cases. But there were some of the tonsillectomy patients who declared they had experienced a recurrence of former inflammation. Certain of these showed small remains, usually at the lower pole, on or in the plica, so that the operation was not truly tonsillectomy. In others no remains could be seen; and the reasonable explanation of their definite statement that tonsillitis had been diagnosed since operation would be that their ailment had really been pharyngitis. The analyses show not only that the absence of evident tonsillar remains does not determine freedom from an infection which may be diagnosed as "tonsillitis," but that, conversely, the presence of such remains does not render such infections much more probable. The explanation of this apparent paradox depends on the situation of the remains, and on certain other anatomical considerations to which allusion will be made under the heading "Lymphadenitis."

Inference from figures obtained.—For tonsillitis, tonsillectomy is the operation of choice; because if as much tonsillar tissue as possible is removed complete in its capsule, there is a greater prospect of permanent cure, and there is no probability of initiating an infection.

Laryngitis and functional voice troubles.—Cases: Tonsillotomy, 26. Result: Cured, 15 (58 per cent.); not cured, 6 (23 per cent.); uncertain, 5 (19 per cent.). Cases: Tonsillectomy, 29. Result: Cured, 14 (48 per cent.); not cured, 14 (48 per cent.); uncertain, 1 (4 per cent.).

Analysis of complaints.—A. Singing voice: the usual trouble is weakness, either of the middle register where head-notes change to chest-notes, or of the notes at the top of the compass. B. Conversational or oratorical voice becomes thick, husky, or hoarse. C. Conversational or oratorical voice is weak, so that when used it either suddenly breaks or rapidly becomes fatigued. D. Intermittent aphonia, partial or complete. By subdividing each of these classes into cases cured, not cured, and arisen afresh since operation, I have found that for Class D there is no great advantage in either operation, and for Classes A and C tonsillectomy is better. But Class B, where the speaking voice becomes thick, husky, and hoarse, comprises more cases than all the other classes added together, and in this class the figures are as follows:—Tonsillotomy: Cured, 65 per cent.; not cured, 15 per cent.; uncertain, 20 per cent. Tonsillectomy: Cured, 25 per cent.; not cured, 69 per cent.; uncertain, 6 per cent.

As regards recurrence of voice troubles, it was mentioned above that these are the only complaints in which recurrence is quite as probable after tonsillectomy as after tonsillotomy. As far as these cases are concerned, therefore, it appears from the gross figures that tonsillotomy has proved the operation of choice, and tonsillectomy is much less suitable. The failure to cure, or fresh supervention of, voice troubles after operation is in some cases referable to deformities produced by the operation. But the cases where this failure or sequela occurs without any demonstrable deformity are, after tonsillotomy 27 per cent., and after tonsillectomy 48 per cent. We must therefore inquire into the relative advantages of partial or total removal of the tonsil for acoustic purposes. With this object it was necessary to eliminate all cases which showed any such deformity as might account for failure to cure voice troubles. The remaining cases were dealt with as follows. The cases cured of voice troubles by tonsillotomy, and also those cured by tonsillectomy, have been divided into those exhibiting and those not exhibiting tonsillar remains at examination. The cases not cured by one or other operation, or in which voice troubles arose only since operation, have been similarly divided. The result is striking. Of the cured cases, whether total or partial emptying of the tonsillar fossa was intended by the operation, nearly one-half present considerable tonsillar remains; whereas the percentage proportion of uncured cases is nearly twice as great after tonsillectomy as after tonsillotomy.

It is a fact that in any room or hall two pillars jutting out from the wall thus—  interfere more with sound-waves than a single wide buttress or plateau of the same width and depth, thus—  And it seems possible that, after tonsillectomy, the two projecting tonsillar pillars, enclosing between them the deep concavity of the empty fossa, may have a similar effect. Possibly also, if the patient have to use the voice much, he may seek to counteract this impediment to free reverberation by more vigorous voice-projection, this fatiguing the laryngeal muscles. It may be argued that, after tonsillectomy, the pillars in course of time become less prominent, and the fossa levels up, so that the surface approximates to a plane. But the average length of time since operation which had elapsed when the cases of uncured or fresh voice troubles were examined was 1 year and 5 months. In none of them did the tonsillar region at all resemble a plateau, and for the voice to be injured for even this period of time may be a serious matter.

Inference from figures obtained.—Of the two operations, tonsillotomy is more likely to cure functional defects of voice, and less likely to leave such a sequelæ.

Lymphadenitis.—Three lists were made, of cases: (1) Exhibiting enlarged glands at the time of operation; (2) exhibiting enlarged glands at subsequent examination—i.e., three months to four years after operation; and (3) exhibiting tonsillar remains at subsequent examination. Cross-classifications of these three lists showed how far they overlapped—i.e., how often "glands before operation," "glands after operation," and "tonsillar remains," occur or do not occur in a given patient. An obvious lingual tonsil was found in only two cases, and any mention of remains has reference to the faucial tonsil. The figures are in favour of tonsillectomy.

Lymphadenitis uncured by operation: Tonsillotomy, 43 per cent.; tonsillectomy, 33 per cent. Lymphadenitis which had never occurred prior to operation and which was found at subsequent examination, all other possible infective foci being excluded: tonsillotomy, 30 per cent.; tonsillectomy, 20 per cent. Now it seems fair to assume that when lymphadenitis is due to an infection from a tonsil or part of a tonsil, this infection must be homolateral on the same side as that tonsil. In investigating this point it was necessary to eliminate all cases in which either glands, remains, or both, were bilateral. It was found that a homolateral infection of glands, occurring only since the operation, was much more frequent after tonsillotomy. The contralateral cases—i.e., where tonsillar remains are found only on one side and enlarged glands only on the other side—occurred with one exception after tonsillotomy. In other words, the infection of glands from an empty tonsillar fossa occurs more frequently when the guillotine has been used in the old-fashioned way than by any other method. To explain this we are reduced to mere speculation. After tonsillotomy, as ordinarily interpreted, the capsule is left behind, whether any tonsillar remains keep it company or not. And it is possible that after a very thorough tonsillotomy, leaving no macroscopic remains, the capsule keeps the fossa stretched open, and so more prone to absorb irritants or micro-organisms. Or that after a still more thorough tonsillotomy the guillotine in certain places cuts deeply, well beyond the capsule, freely opening up the areolar tissue, which subsequently heals by the formation of granulation tissue too loose and thin to resist septic absorption. It is noteworthy that tonsillar remains, after either operation, were found more often on the left side. This may be due to the attitude of the surgeon or because his view of the second tonsil attacked is impeded by hæmorrhage.

One other point calls for mention concerning lymphadenitis in its relation to tonsillar remains. The latter existed sometimes for the whole length of the tonsillar fossa, at other times as a nodule at the top or bottom. First the cases in which remains occurred at only one pole were picked out, and then this list was still further reduced by selecting only such as showed a homolateral lymphadenitis. The figures thus obtained bring out a curious fact. For, whereas it is in some cases fair to accuse a solitary remaining lower pole of infecting glands, in no case can this charge be laid against a solitary remaining upper pole. Since no known distribution of efferent lymphatics can explain this, I offer the following hypothesis. In cases where, subsequent to operation, pyo-alveolaris or other infection of the oral mucosa occurs, infected saliva and mucus reach the lymphatics by falling by gravity into the most dependent part of the fossa; here, moreover, the plica triangularis tends to lock them up. Whereas, when tonsillar remains are limited to the uppermost part of the recess, infected saliva comes into contact with them later and for a shorter period of time. This suggestion applies to the occurrence after operation of not only lymphadenitis, but also of tonsillitis.

the condition shown in Fig. 3 will be produced—that is to say, the penis will be straight, and there will be a broad raw surface on the under aspect, at the scrotal end of which the urethra opens. The detached urethral groove does not remain as an elongated flap, but contracts into a surprisingly small mass (Fig. 3, *b*). An incision is then made on each side from the anterior portion of the raw area around the corona glandis, and about a millimetre away from this structure until the middle of the preputial flap is reached, when the direction of the incision is altered and it is carried along the long axis of the flap up to the free edge which was made by dividing the buttonhole (Fig 3, *c*). This incision should extend just through the skin, and it will then be possible to open out the lax tissues so as to produce the conditions shown in Fig. 4; this should be done with as little actual division of tissue as possible.

FIG. 6.

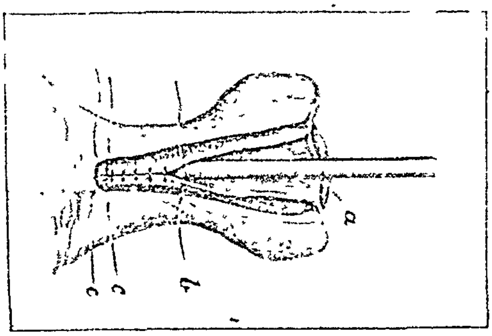
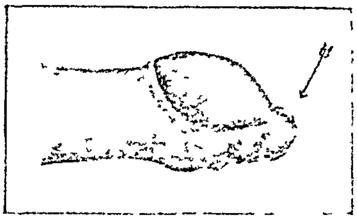
FIG. 7.



The third stage of the operation. *a*, Catheter stitched into meatus. *b*, Deep sutures (catgut). *c*, Superficial skin sutures (horsehair).

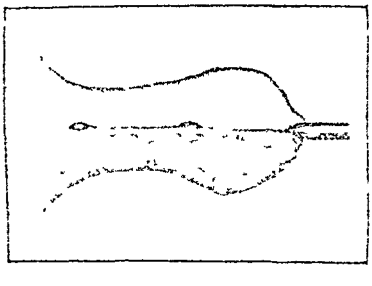
FIG. 8.



The completed operation. The arrow points to the urethral orifice

The next proceeding consists in passing stitches so as to slide in skin from the preputial flaps and thus cover the whole of this raw area with epithelium, part of which will ultimately line the new urethra. It is well to pass a stitch through the glans so as to hold the organ straight before passing the sutures. The first of these (Fig. 4, *b*) is placed so as to pick up the point of the shrunken urethra; the next (Fig. 4, *b'*) passes through the skin on one side, takes a hold on the fibrous tissue of the raw area, and finally emerges through the skin on the opposite side; the remaining sutures are passed similarly, the flaps being brought as far towards the orifice of the urethra as can be done without puckering. It will usually be found that the points *c c* (Fig. 4) will be sutured to the raw surface, just below the stitch which has been passed through the glans. The appearance when all these stitches have been passed is seen in Fig. 5. On the lateral aspect of the glans there is still a line along which the epithelium is not united, and this should now be done by a row of sutures (Fig. 6). This completes the second stage of the operation, and when the wounds have healed it will be found that the penis is perfectly straight and considerably broader, especially in the region of the glans.

FIG. 9.



To show the most common position in which fistulæ form.

FIG. 10.

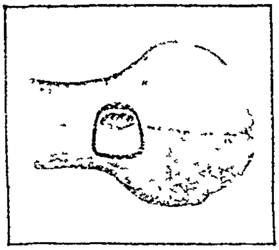


FIG. 11.

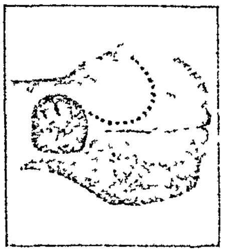

FIG. 12.

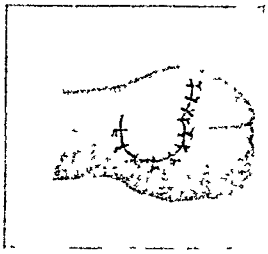


FIGS. 10, 11, 12.—Method of closing a fistula.

Stage 3.—At least another three months should be left before commencing this stage of the operation, which is carried out almost exactly as in Duplay's operation. A soft rubber catheter is passed into the urethra and stitched to the middle line of the glans (Fig. 7, *a*); this steadies the organ and facilitates the rest of the operation. An incision is made on either side of the urethral channel, extending into the connective tissue, which is then sutured around the bougie by a row of stitches (Fig. 7, *b*); the skin is closed over this by another row of stitches (Fig. 7, *c*). At the anterior part care should be taken to make the incision run slightly outwards, so as to make the floor of the urethra slightly longer than the roof; this allows for shrinkage.

The operation is now finished, and the appearance of the penis is that of an organ which has been circumcised, leaving a rather redundant mass of tissue below the frenum (Fig. 8). If everything heals satisfactorily the operation is completed, except that there will usually be a few rather unsightly tags of skin at the side of the glans, which can be clipped away if desired; but this should never be done until sound union has been obtained, as these tags will prove extremely valuable if it should be found necessary to perform any further plastic operation for closing a fistula. Fistulæ most commonly occur either at the junction of the body of the penis with the glans or just in front of the scrotum, and they are best closed in the manner shown in Figs. 10, 11, and 12. An incision is made round the fistula in the manner shown in Fig. 10, in which it will be noticed that the incision is not symmetrically placed in regard to the fistulous opening, but is well to one side, so that a flap is raised, which can be turned over the opening and sutured in position (Fig. 11). The free edge of this flap should be distinctly longer than the fistulous opening, so as to allow for shrinkage and for the insertion of sutures. When the flap has been fastened in position a raw surface is left, which is closed by sliding in a curved flap, as marked out in Fig. 11, the whole being sutured into position. This flap will usually be composed of the redundant tissue on one side of the glans, which will now present the appearance shown in Fig. 12. In the case of fistulæ at the root of the scrotum double flaps are cut as before, but the second flap is derived from scrotal tissue.

As regards suture material I have always employed fine chromicised catgut, except in the case of the final skin sutures, for which I have used horsehair. The parts are extremely delicate and friable, and it is therefore necessary to use fine needles, preferably ordinary sewing needles or curved intestinal needles. Accuracy in suturing is, of course, indispensable, but it is equally important to get a good hold on the skin flap, so that the stitches will not cut out when they are moistened with urine. As regards dressings, strips of moist boric lint wrapped round the organ and changed as often as they are soiled with urine are probably the most satisfactory, and are certainly the most comfortable for the patient. I have not found any particular advantage in keeping a catheter tied in to prevent the passage of urine over the wound. An instrument tends to set up urethritis and to keep a certain amount of tension on the stitches; furthermore, it does not always succeed in keeping the wound dry, as urine is apt to leak by the side of it.

The operation can be performed at any time after the age of 3, but it is certainly easier when the boy is older, as the parts are larger and simpler to handle. In the cases which I have completed the results are extremely satisfactory. The urine is passed freely and projected forwards in a satisfactory stream, the straightness of the organ being all that could be desired. The new lining of the urethra, as seen in those cases in which a fistulous opening formed, seems to have taken on the character of mucous membrane. I have now operated on five cases; two are completely healed, one has a fistulous opening which remains to be closed, and in two the third stage has not yet been attempted; in all, however, the straightness of the organ is entirely satisfactory.

Queen Anne street, W.

ON A CASE OF ADDISON'S DISEASE IN A BOY AGED TEN YEARS.[1]

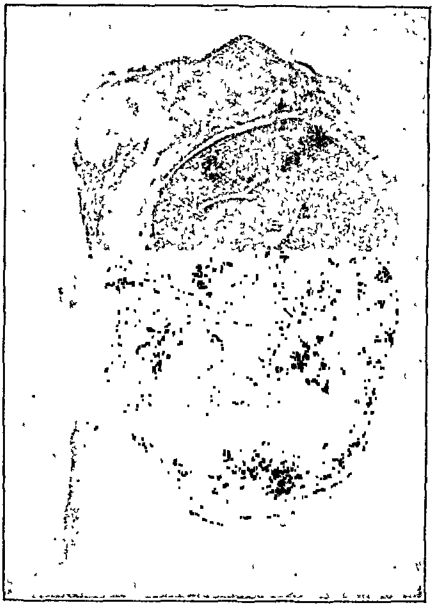
BY FREDERICK LANGMEAD, M.D. LOND.,
M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE ROYAL FREE HOSPITAL; THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET; AND THE SEAMEN'S HOSPITAL SOCIETY (DREADNOUGHT), GREENWICH.

DEFINITE cases of Addison's disease in children are without doubt very rare. In the annals of the Hospital for Sick Children, Great Ormond-street, no record appears of a post-mortem examination on a patient who had been the subject of this disease, nor is there any clinical record of a case in which the symptoms were convincing enough to make the diagnosis more than questionable. Comby has collected 21 cases in children, and Dezirot 48 cases in children under 16. Of these, only 6 were under 10, the majority being in the eleventh and fifteenth years of life. Osler records an example of the disease occurring congenitally. Monti was able to find records of 11 cases in children from 3 to 14 years old. The disease in children would appear to produce symptoms very similar to those occurring in adults. Although protracted cases are described, a greater proportion run a very acute course in children. Apparently the pigmentation is usually less obvious than in the majority of adult cases, although, as is well known, a few of the latter show little or no darkening of the skin or mucous membrane. Death from convulsions and coma would appear also to be relatively more frequent in children and death from asthenia relatively less. According to Gerhardt convulsions are seen in two-fifths of the cases in children. Netter describes a case in a child, aged 4 years, who was suddenly taken ill with vomiting, diarrhœa, and depression, and died in three days.

The following case has many interesting features. The patient, a boy aged 10, was admitted to the Royal Free Hospital on Sept. 17th, 1912, at 6 A.M., and died four hours after admission. On the evening before, vomiting had started abruptly, accompanied by restlessness, and followed by loss of consciousness. On admission he was seen to be unconscious, the elbows, wrists, and knees being rigidly flexed, and the fingers extended. The temperature was subnormal and the pulse rapid and weak. The abdomen was retracted. The knee-jerks were present, and the plantar response was flexor. Frequent convulsive seizures occurred until death.

The case gave rise to much conjecture as to its nature, and remained undiagnosed until the post-mortem examination. A possible explanation appeared to be meningitis, but the rapidity of its course was against this view. Moreover, the optic discs were normal, and cerebro-spinal fluid withdrawn by lumbar puncture showed no abnormality beyond absence of reducing power. The possibility of uræmia was excluded by the fact that a catheter specimen of urine was normal. Acetone was not present, an observation which excluded "cyclical vomiting" from the diagnosis. The pigmentation amounted to no more than a slight diffuse brownness of the skin, including that of the abdomen, and would not give rise to comment in a child of the poor at the end of the summer. Later it was learnt by careful questioning of the mother that the pigmentation had been noticed to have gradually deepened for about 12 months, and that the boy had been subject to attacks of diarrhœa for "several months," and had been slowly getting weaker. The boy's father had died from phthisis ten years before, and two aunts and one uncle of his mother also died from the same disease.

Necropsy.—The body was that of a somewhat wasted boy, the skin showing slight general pigmentation without maculæ.



From a photograph of one kidney and suprarenal gland showing the advanced stage of the fibro caseous change. The other was similarly affected. (Photograph by Miss Katherine Wortham.)

The suprarenal glands were fibro-caseous, almost throughout, merely a narrow margin of healthy gland tissue being discernible, and this only in a few areas (see figure). The fibrosis had spread into the adjoining posterior abdominal parietes, and must have involved the sympathetic ganglia, though these were not recognised. Caseous glands were found in the portal fissure and two caseous foci in the lowest lobes of the lungs, near the roots, probably representing glands also. Microscopically the tuberculous nature of the process was apparent. Many large giant cell systems and tubercle bacilli were seen. There was very considerable overgrowth of the lymphatic structures. The thymus, tonsils, lymphatic patches of the tongue and intestine, and the mesenteric glands were all hyperplastic, as in status lymphaticus. The spleen was considerably enlarged, reaching well down into the abdomen almost to the umbilicus, and weighing 5 oz. The pancreas, thyroid, thymus, spleen, and pituitary body were examined microscopically, but showed no abnormal change in their structure.

---

[1] The specimen was shown at the Medical Society of London on Jan. 27th, 1913.

An especially interesting feature was the small size of the heart, which weighed only 3 oz. Its smallness attracted attention immediately after removal of the sternum and ribs, and it resembled in size more the heart of a child of two or three years old. This is only what is to be expected, considering the low degree of blood pressure which the boy must have had for some considerable time. It can, I think, properly be regarded as a true hypoplasia due to the little work which the heart was called upon to perform. In adults atrophy of the heart has often been described, but I have not encountered a description of cardiac hypoplasia in Addison's disease in children.

Queen Anne-street, W.

POLYCYSTIC DISEASE OF KIDNEYS:

REMARKABLE PERSISTENCE OF FUNCTIONS IN TWO CASES IN ADULTS.

By H. RISCHBIETH, M.A., M.D., B.C. CANTAB., F.R.C.S. ENG.,

AND

C. P. C. DE CRESPIGNY, M.D., B.S. MELB.,

PATHOLOGIST, ADELAIDE HOSPITAL, SOUTH AUSTRALIA.

THE two following cases of polycystic disease of the kidneys appear to be of sufficient interest to warrant recording. They offer contrasts in their clinical histories, morbid anatomy, modes of exitus, and it might be suspected in their mode of origin. The clinical histories of these cases were furnished by Professor A. Watson, of the University of Adelaide, by whom their publication was suggested.

In the first case the patient, a male, attained the age of 26 years without a symptom. He then had an attack of intestinal obstruction of a subacute and partial kind, and on examination a tumour was revealed, which was at first thought by his medical attendant to be a tumour of the descending colon. The tumour was subsequently diagnosed as renal, and on operation proved to be a polycystic kidney, which was removed. The right kidney was also ascertained at operation to be polycystic. The patient remained in perfect health for six years with one polycystic kidney, had no symptoms suggestive of renal disease, was passed for life insurance, and died from an independent disorder—acute septic meningitis secondary to otitis media, and as far as his renal functions were concerned might have lived for many years more. He showed an associated defect in an abnormality of the heart, and it might be supposed that this case was "congenital" in origin.

The second case was admitted into the Adelaide Hospital at the age of 62 years suffering from acute colitis, from which he died, and both kidneys were found to be polycystic on post-mortem examination. There was a history of gout, with a first attack at the age of 30 years, and of beer drinking; and at the age of 62 years there was some not inconsiderable arterial degeneration, with, however, but little ventricular hypertrophy; but there had never been any symptoms suggestive of renal disease. And this type of case, if any, might perhaps be considered to have been "acquired." No facts upon the point of family or hereditary relationships could be obtained in either case; for no relatives could be traced. The kidneys of these two cases are shown in the accompanying figures.

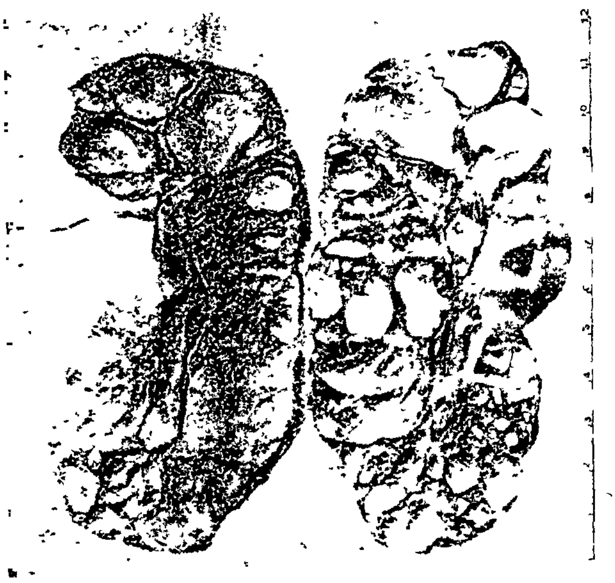
CASE 1.—The patient, a man aged 27 years, was sent to the Adelaide Hospital by his medical man at Port Pirie as suffering from tumour of the descending colon.

History.—Fourteen days previously the abdomen became distended and the patient was unable to pass anything by the bowel. After enemata he passed flatus and was somewhat relieved. No vomiting. On the third day of illness a lump was observed by the medical man in the left side below the ribs. It caused no pain, but was somewhat tender on palpation. The patient vomited once on the fourth day. The bowels were not opened for the first seven days; after this they were regular. The motions at first contained a little slime and blood. Appetite *fair; no jaundice. He had never* had any pain suggestive of renal colic, nor any trouble with his urine. This had never been noted to be blood-stained or to contain "gravel."

Previous illnesses.—Ruptured since 13 years of age; had always worn a truss. "Catarrh of bowels" four months previously. Left pleurisy two years previously. Slight traces of plumbism (had been working as a smelter for six months). No syphilis.

Physical examination on admission.—Temperature, 99·3° F.; tongue moist, furred; breath offensive; pulse-rate 76, of medium volume and tension. On the buccal surface of the lower lip, on the left side in the region where the incisor teeth came into contact with it, there were several sloughy ulcers; these were painful. The lip was swollen and the gums were soft and congested. No physical signs in heart or lungs. In the left side of the abdomen, immediately below the costal margin, a distinct, smooth, hard, rounded, oblong tumour could be felt, lying in the flank. The fingers could be got below this tumour but not above it. It was easily felt bimanually, was fairly fixed, did not move appreciably on respiration, was defined clearly internally, and was slightly tender on palpation. Intestine could be made out anterior and internal to it. No abnormality could be detected on the right side of the abdomen. Urine acid, 1008, clear, pale; contained a faint trace of albumin, no sugar, and no deposit.

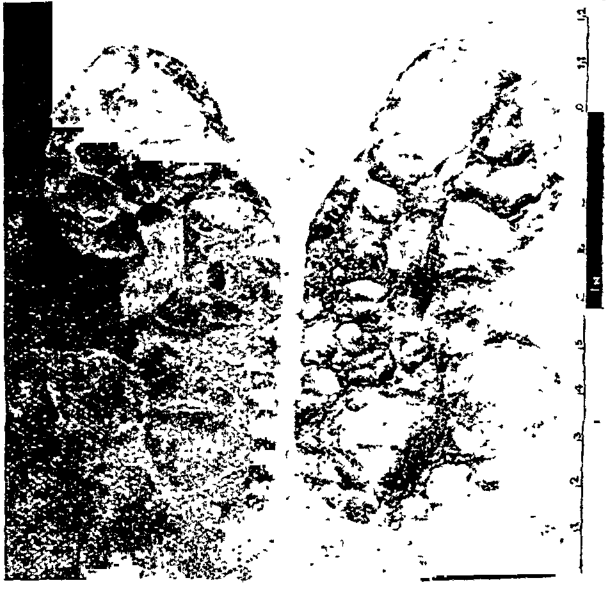
FIG. 1.



Case 1.—Right kidney polycystic.

Two days after admission this tumour, the left kidney, was removed. It was completely cystic. Its maximum measurements were 12 by 6 by 3 in., and it weighed 5¼ lb. A photograph, taken after nearly seven years in spirit, of this kidney, marked 1905, is reproduced. (Fig. 2.) On operation (Nov. 16th, 1905) the right kidney was also recognised as much enlarged and polycystic. There were no cysts in the liver or spleen, both of which were examined.

FIG. 2.



Case 1.—Left polycystic kidney.

The patient was shown at a meeting of the South Australian Branch of the British Medical Association 14 days after operation, and discharged to convalescent home 11 days later. His weight was then much increased (it had increased by 5 lb. in the last week). He was then passing on an average 97 oz. of urine of low specific gravity (1002) in the 24 hours.

The patient had to be readmitted four days later by reason of an attack of pneumonia, from which he eventually recovered. The urine then had a specific gravity of 1010, and contained a faint trace of albumin. Seven days later the qua [illegible] the 24 hours, was acid, 1008, contain [illegible] sugar, and no deposit. Owing to the [illegible] been removed too soon (i.e., two days [illegible] lumbar stab-drain incision gave way [illegible] admission, and an abscess was ov [illegible] uneventful.

The subsequent history of this individual was as follows. He remained in good health for some six years, and was during this time passed for life insurance, the scar of the abdominal incision having escaped observation. Some six years later, however, he was readmitted to the Adelaide Hospital suffering from acute septic meningitis, secondary to otitis media, from which after operation he died. The urine then had a specific gravity of 1015, and contained a fair cloud of albumin.

Necropsy.—A complete post-mortem examination was performed. [illegible] from the cause of death, septic [illegible] were *comparatively unimportant* [illegible]

[illegible] (weight proved to be 70 oz) and pushed forwards and to the left, the gall-bladder being situated in the left [illegible]

[illegible] (Fig. 1.) A good deal of shrinking has occurred owing to the prolonged immersion—more especially of the 1905 specimen—of these viscera in preserving fluids, probably an inch or more in the longest diameter.)

It is stated that *the nutrition of this body was good*, and this may be regarded as an indication that the general health of this individual had suffered little from the deprivation of [illegible] maining [illegible] at least [illegible] r family factors in this case nothing can be ascertained, for no relatives can be traced.

CASE 2.—The patient, a man aged 62 years, was admitted to the Adelaide Hospital on July 14th, 1910.

History.—The patient had been quite well until 15 [illegible]

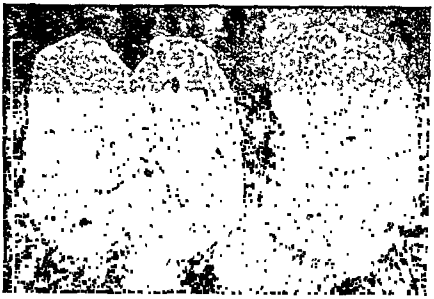
[illegible] or two previous attacks like the present, but they were slight and only lasted an hour or so. No other illnesses.

Family history.—Married, 8 children, 5 dead. First and third [illegible]

Physical examination.—A thin man of poor general nourishment. Prostration marked. Tongue coated and dry; teeth very foul; marked pyorrhœa alveolaris. Temperature subnormal; pulse 120, of [illegible] arterial wall very much thickened. [illegible] impalpable; by auscultation it [illegible] space 1 inch internal to the [illegible]. Heart sounds rather weak; [illegible] ous. Abdomen: No distension or rigidity; slight tenderness in the right hypochondrium; liver slightly enlarged downwards to 1 inch below the costal margin. Motions: Pea soup stools containing reddish flocculi and a very little mucus. Death in coma. Urine: No note.

Necropsy.—[illegible] sli [illegible] at [illegible] of [illegible] pa [illegible] congested and [illegible] membrane of the cæcum was [illegible]

FIG. 3.



Case 2.—Polycystic kidneys.

scarring of the mesentery. Both kidneys were large, polycystic, and the renal substance was diminished. (Fig. 3.) Both suprarenal glands were normal.

Thus the cause of death was exhaustion and coma, in acute colitis. The polycystic condition of the kidneys appears to be an independent association. Or is it to be regarded as a terminal infection in a chronic uræmic state? Or are we dealing, perhaps, with chronic interstitial nephritis in addition, in a gouty beer-drinker? Or is the polycystic degeneration the result of this chronic inflammatory condition? Except for size and for the fact that the perirenal fat is increased and that there is proportionately more renal tissue, the kidneys of this case much resemble those of Case 1. The vessels are small and show little thickening of their walls or atheromatous degeneration. Nothing can be ascertained upon the subject of possible heredity or family factors in the case, for here again no relations can be traced.

The following points with regard to the macroscopical appearances of the kidneys of these cases should be stated. In Case 1 the pelvis in both is enlarged commensurate with the great size of these kidneys; but there is, otherwise, nothing to suggest dilatation. Neither ureter is dilated. The vessels are in no way enlarged and there is no increase of pelvic fat. The capsule strips without any difficulty. In Case 2 the pelvis is not perceptibly dilated in either; neither ureter is dilated. The pelvic fat is somewhat increased. No abnormality in the vessels can be observed. The arteries are small, very little thickened, and not atheromatous. The capsule *strips with very slight difficulty, but this is not* greater than is not infrequently seen in the kidneys of individuals of this age (62 years) which are not regarded as morbid.

The points of interest in these cases appear to be:—In Case 1: (*a*) The age, 26 years, at which the condition first became manifest. If this condition was congenital in origin, as is to some extent suggested by the fact that this patient showed what appeared to be a congenital abnormality of the heart as well, it is perhaps remarkable that kidneys of this size and degree of cystic degeneration should not have caused *symptoms*, renal or other, earlier in life. (*b*) That the first symptom produced was intestinal obstruction; this, however, is not very surprising, considering the size to which these tumours had attained. (*c*) That one kidney of the type here shown should be capable of maintaining the renal functions and warding off symptoms of renal insufficiency for some six years and maintaining perfect health. This individual was passed for life insurance having only one kidney, and that polycystic, and appeared to be in good health up to the time that one of the complications of otitis media carried him off. (*d*) Again, the age is peculiar when statistics of published cases are considered, for it is unusually old or unusually young.

---

* If this is to be regarded as a [illegible] congenital polycystitis.

The points of interest in the second case appear to be:— (*a*) The age, 62 years, to which this individual attained with kidneys such as those shown without suffering symptoms suggestive of renal disease. This, however, is not uncommon in this condition. (*b*) The problem, Was the acute colitis from which this man died a terminal infection in a chronic uræmic state, or an independent condition? For the evidence of uræmia was very slight. (*c*) The possible part played by gout in the causation of the polycystic degeneration of the kidneys in this case. That is to say, Are we dealing with a *congenital* condition in a man, aged 62 years, the result, let us say, of embryonic failure of union between secreting and conducting parts of the kidney (which has, however, given rise to no symptoms for so many years)? Or is the condition acquired, the effect of, let us say, fibrous proliferation around the tubules, exudation into them, or cicatrisation after nephritis, causing obstruction of the urinary passage (as Morris suggests), and possibly in this case the effect of gout? Any of these causes might cause a polycystic condition such as these kidneys show. (*d*) If the acute colitis from which this man died was a terminal infection in a uræmic state, are we to regard the latter as that of the last stage of polycystic disease or degeneration of the kidney? Or is it to be considered as that of chronic interstitial nephritis, of possibly gouty origin, affecting a kidney already polycystic? (*e*) Or is the condition, *in toto*, one of polycystic degeneration of a granular kidney? There is no note of the condition of the urine. But since the urine may have much the same characters in all the above conditions, its diagnostic value here would not be great. These kidneys show little indication of chronic interstitial nephritis in fibrotic changes, and do not resemble any specimens of cystic granular kidney that one has seen. Further, the arteries are rather small, very little thickened, and not atheromatous. The hypertrophy of the left ventricle was very slight, arterial tension not very markedly increased, and the degree of atheroma and arterial degeneration that was present not more than would be fairly often seen without symptoms in an individual of this age who, like this man, had been a manual labourer all his life. Therefore the hypothesis that chronic interstitial changes, the effect of gout, may have played a leading part in the causation of the polycystic disease of these kidneys must be abandoned. They would seem to be examples of "polycystic degeneration," whether they be congenital in origin or arise from some unknown cause occurring in adult life.

The appearances, macroscopical and microscopical, the clinical features and types of cases, duration of life, frequency and sex incidence of polycystic disease of the kidney, have been very fully described. It is not proposed here to describe anew the structural features as shown by the kidneys of these two cases. But in order to place these in their proper groups a summarised review of the literature seems advisable. For it is in the pathogenesis, at present wrapped in obscurity, and in the clinical features, one and another, of cases that the chief difficulties seem to be.

Frequency.—Garceau quotes Preitz, of Kiel, who found 16 cases of polycystic disease of the kidneys in 10,000 necropsies, or 0·16 per cent. In the records of the Boston City Hospital (1896 to 1906) there were 10 cases in 2429 necropsies, or 0·041 per cent.

Age incidence: that is, time when first observed.—Senator[1] states: "The condition may be seen in the fœtus—i.e., it is congenital—the chief feature of importance being difficulties which it causes in parturition." To this well-known condition Morris,[2] Bland-Sutton,[3] and Garceau[4] also refer in their accounts, which agree in all points. Garceau quotes Boinet and Raybaud, who give a list of 35 cases in infancy of ages from full term to six months of age. Garceau and Senator both state that the disease is more commonly one of middle life, and most cases occur during the fifth decade. (Whether the condition, then, is congenital or acquired is difficult to decide) (Senator, Garceau.) Bland-Sutton, on the other hand, appears to regard all cases in the adult as congenital in origin, while Morris appears to regard cases in adults as acquired. Before the third decade the condition is very rare (Senator). It seldom occurs between infancy and 21 years (Garceau). Senator quotes Luzzatto on this point; the latter observer found only two cases developing between the tenth and twentieth years out of 187 cases. Garceau quotes Seiber, who in 173 cases found the age incidence as follows: Third decade, 26 cases; fourth decade, 22; fifth decade, 67; sixth decade, 40; seventh decade, 10; eighth decade, 6; ninth decade, 2.

Sex incidence.—Senator and Morris state that in adults the condition is commoner in males—"a little more than half." Garceau, on the contrary, states that women are more frequently affected than men, and quotes Seiber, who found, in 198 cases in which the sex was stated, 116 females and 82 males. In the operative cases he states that this proportion is much higher. Thus Seiber found in 70 cases in which an operation had been performed 60 women and 10 men. Albarran and Imbert found in a series of cases 35 women and 10 men.

Unilateral or bilateral?—Nearly always bilateral. Senator quotes Lejars, who found the condition to be unilateral in 1 case out of 60, and Luzzatto whose figures were 41 out of 226.

According to Garceau, there is some preference for the left side, for Seiber in 9 unilateral cases found this to be the left side in 6, and in 46 cases operated upon the figures were 28 left and 18 right.

Hereditary and family cases have been reported by Steiner and Höhne, amongst others.

Association with other malformations.—All observers refer to the frequent association of polycystic kidneys with congenital malformations of various kinds: anencephaly, talipes, spina bifida, atresia of prepuce, imperforate urethra, cleft palate, polydactylism, absence of limbs, imperforate anus, absence of bladder, occlusion of ureters, absence or occlusion of pelvis of kidney, double vagina or uterus, &c. The polycystic condition of the kidneys is also frequently associated with a similar cystic condition of the liver. Senator quotes the figures of Lejars, who found the liver affected in 17 of 60 cases, and those of Luzzatto, which were 19·1 per cent.

Pathogenesis.—Some authorities regard *congenital* cystic kidney as an altogether different condition from the polycystic condition of the adult. Of these, Morris appears to be one. Bland-Sutton, on the other hand, appears to regard them as the same. Senator remarks, however, that the manner in which cyst formation occurs is as obscure in the one case as the other. Garceau regards the condition in the adult and in the infant as having the same pathogenesis, though the conditions show features which are dissimilar at the two ages, and in the adult in some cases the cysts do not date from fœtal life.

The following theories now hold the field: (1) The process is one of new growth, an adenoma or adenocystoma, just as are the hepatic cysts sometimes found in association with polycystic kidneys. This view is held to be supported by the fact that islands of hyaline cartilage have been found (by von Mutach) in the stroma of a renal cyst. This favours the theory of tumour formation and is analogous to the islands of hyaline cartilage found in testicular adenomata, which develop in close proximity to the kidneys (Senator).

(2) The cysts arise from obstruction of the urinary passages. This was Virchow's view. The obstruction is not to be looked for in the larger urinary passages, from the pelvis downwards—for this is usually absent, and, when present, produces hydronephrosis, except when the obstruction develops late in fœtal life—but is due to occlusion by fœtal inflammation of the lower urinary tubules, such as the collecting tubules by concretions, uric acid, calcareous infarction, proliferation of fibrous tissue around the ducts or exudation into them, atresia of papillæ, due to embyronic papillary nephritis or pyelonephritis, for example. With this view Morris appears to agree, for he states that whether they occur in the fœtus or in the adult the cysts are due to

[4] E. Garceau: Renal, Ureteral, Perirenal, and Adrenal Tumours, &c., of the Kidney, London and New York, 1909, pp. 222–53.

obstruction from some such cause as the above But none of these changes have been found in every case, and therefore the following view is held —

(3) That the obstruction is due to arrested or maldevelopment of the kidney. The frequent association with other malformations is held to support this view, as well as the fact that hereditary and family cases have been recorded This arrest might prevent junction between uriniferous tubules and pelvis being established Ribbert holds that

cyst formation, and that these cysts are of two kinds—those of the glomeruli and those of the extremities of the collecting tubules In adults at any rate, the retention is produced by chronic interstitial inflammatory processes in the region of the pelvis, calyces and medullary portion, leading to distension and obliteration of the uriniferous tubules (Senator, Morris, Garceau)

(4) The theory of maldevelopment or arrested development with subsequent new growth upon this (Garceau)

Clinical classification of cases (Senator) *A In the fœtus* —This condition causes difficulty in parturition, stillbirth or death soon after birth from interference with the action of the diaphragm or from complications from the other malformations

B In the adult —Group I A total absence of symptoms Death from other causes and polycystic disease of the kidneys only revealed at necropsy Group II Cases showing symptoms of renal disorder—i e , urinary symptoms, but *these not characteristic of any definite* condition Group III In these there is a renal tumour In Lejars's figures there were only 18 such out of 62 cases (Senator) In most cases the enlargement of the kidneys is insufficient for it to be detected during life

Characters of the swelling —This resembles hydronephrosis but is usually bilateral Fluctuation less usual, and the condition is usually bilateral

Pain —This, the most prominent feature of the second stage, may be slight or severe, present or absent Very occasionally there are paroxysms like those of renal colic (Senator)

Characters of the urine —This is variable and may be *(a)* normal in quantity and composition, *(b)* scanty and of low specific gravity, *(c)* occasionally neutral or alkaline, *(d)* abundant with or without albumin, or containing blood or rosettes resembling leucin

Other observers have divided the condition into stages thus Stages I , II , and III But this is not a practical division clinically, even if it be correct, for the reason that most cases do not appear to follow "stages" in any way that can be discovered during life "Œdema is occasional, cardiac hypertrophy usual and the case may resemble one of chronic interstitial nephritis' (Senator) "Uræmia is the usual termination" ' The general condition may remain undisturbed or may deteriorate ' ' Cachexia is occasional, but fever rare" (Senator) ' The course extends over years, but lacks uniformity in different cases ' "Among the complications are suppuration of cysts, calculus, hydronephrosis, and tuberculosis" (Garceau) "The onset is insidious and duration over years' (Senator, 20 years , Lejars, 15 years)

Our second case falls into Group I , and our first case into Group III , of the clinical classification of cases suggested by Senator *And the maintenance* of good health in this case for six years with only one such kidney seems the more remarkable, since it is stated by authorities (e g , Senator) that by the time the tumour is obvious the course is usually comparatively short, for the reason that so little renal tissue is by that time left for work

NOTE ON A CASE OF
CHRONIC INTERNAL HYDROCEPHALUS.

BY JAMES RAE, M A , M D ABERD ,
ASSISTANT MEDICAL OFFICER PARK HOSPITAL FOR CHILDREN, HITHER GREEN

THE finding of a clot in the torcular herophili in association with hydrocephalus has apparently not been recorded, and the fact may justify an account of such a case

The patient, a boy aged *4 years 10* months, was the tenth of a family of 13 The father was healthy , the mother "had a cough" and had been an out patient at a chest hospital for several years Three children died from wasting and "consumption of the bowels' , one from convulsions, one from diphtheria, and one was stillborn The patient himself was subject to convulsions during his first year He began to take notice and to talk at about the usual age, and had measles and whooping cough Shortly before his fourth birthday he seemed to become stupid, and at this time his parents thought his head was enlarging He was admitted to Lambeth Infirmary on Dec 14th 1911, and transferred to the Park Hospital for Children, Hither Green, on Nov 27th 1912 On admission his head measured 22¾ in in circumference, and the anterior fontanelle 2¼ in laterally The chest had marked rickety deformities, with an angular projection on the ninth rib of each side just outside the nipple line The arms were spastic and the hands clenched The frontal and the right angular veins were very prominent, and when the child cried the external jugular *veins became half an inch in diameter On the* evening of admission signs of pneumonia appeared on the right side, subsequently extending Death took place on the tenth day after admission

Necropsy —A post mortem examination was made 24 hours after death The right lung was in a state of red hepatisation , the lower lobe of the left lung showed a few scattered tubercles Four bronchia
enlarged and caseating, t
No other tuberculous foci
no pleural adhesions, and not more than 2 drachms of clear yellow fluid in the pericardial cavity When the meninges of the brain were opened a large quantity of clear fluid escaped, and continued to drain away when the brain was removed The cerebrum weighed 31' oz , and when opened out measured 13⅜ in from edge to edge Its cortex was ⅜ in thick, and the corpus callosum ⅛ in , the fornix being a mere film The cornua of the lateral ventricles had the following depths posterior, 1¼ in , anterior, just under 1 in , lateral, only ¼ in The cerebellum medulla and pons together weighed 3¾ oz The veins of the cerebellum and those passing through the right foramen cæcum were much enlarged and tortuous The Sylvian veins also were distended, particularly on the right side The lateral sinuses measured 1 in in diameter, the occipital sinus ⅝ in at its posterior end, and the internal jugular veins ¾ in

The torcular herophili contained a pyramidal blood clot, lying with its apex towards the straight sinus When fresh the clot weighed just under ¼ oz , was 1⅜ in high, and 1 in across its base Its outer surface was a dark golden yellow, except for a deep crimson layer at the base, 3/16 in deep The cut surface was visibly laminated, deep pink in the centre growing paler towards the periphery

This clot is now in the Museum of the Royal College of Surgeons of England, and Mr S G Shattock has kindly sent me the following report on it "As viewed in section the clot is at one pole of a bright red colour , the rest, and by far the chief portion, is devoid of colour, and has a flexible, finely sponge like character Histologically the uncoloured portion consists of a somewhat open felt or tangle of fibrin filaments Scarcely any red cells are present in the meshes,

blood, but this merges into the structure just described, the number of red cells diminishing in the meshes of the fibrinous stroma, until practically none are to be encountered There are no vessels in any part of the coagulum, and no fibroblasts—i e , no organisation is in progress '

As has been stated above, no similar case appears to have been recorded. D'Astros,[*] in the section of his monograph which deals with venous obstruction, does not mention the formation of such clots. Browning[†] has reported the discovery of an organised thrombus, ⅓ in. long, lying in the straight sinus, with another in the longitudinal sinus (? superior or inferior) in a less advanced condition. His patient was a girl aged 6, who died three months after hydrocephalus was first observed.

Hither Green, S.E.

THE ACTION OF SCHARLACH R UPON X RAYED SKIN.

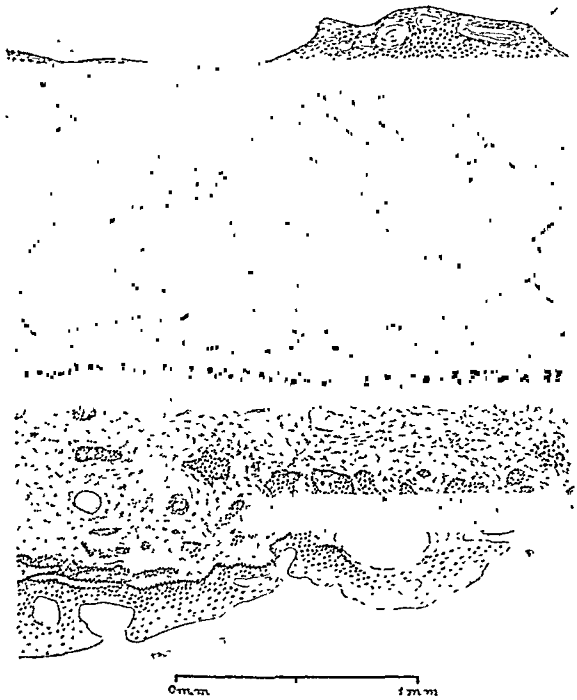
BY J. O. WAKELIN BARRATT, M.D., D.SC. LOND.

(From the Cancer Research Laboratory, The University, Liverpool.—Mrs. Sutton Timmis Memorial.)

IN previous communications the condition of mitosis in epithelium caused to proliferate by the action of Scharlach R[1] has been studied, and also the course of events following upon implantation of such epithelium.[2] The present paper deals with the effect of injection of Scharlach R into the skin of the ear of the rabbit exposed, 2 to 15 months previously, to the action of X rays. In such cases the full destructive effect of the X rays has been produced and the skin has again passed into a stationary condition.

It will be of advantage to study first the change produced by Scharlach R in the X rayed skin of the ear when the amount of destruction effected by the action of X rays has not been sufficient to produce complete disappearance of all the appendages of the skin. These changes are illustrated in Figs. 1 to 4,[3] which are made from two rabbits (A and B) similarly treated. The changes induced by the action of X rays in these two rabbits were of long standing, having been set up 15 months previously, so that at the time of injection of Scharlach R about 80 per cent. of the hairs had disappeared from the portion of the ear X rayed, those remaining being free from pigment, and shorter and finer than those present before the application of X rays. The skin of the ear was thinner than normal, pale and smooth, presenting a somewhat scarred aspect and exhibiting irregular areas of increased pigmentation alternating with areas nearly free from pigment. These changes were more marked on the outer aspect of the ear than on the inner.

FIG. 1.

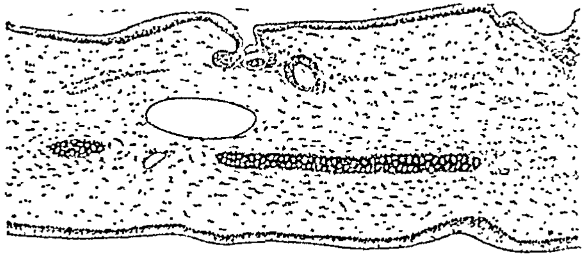


(The scale of Figs. 2 and 5 is the same as that of Fig. 1.)

Section of ear of rabbit A, exposed to the action of X rays 15 months previously. Scharlach R dissolved in olive oil was injected beneath the skin of the outer surface of the ear and later a portion of the injected area was removed for sectioning. Considerable epithelial proliferation has occurred chiefly, but not exclusively, in the epithelium of the outer surface of the ear. Both surfaces are irregular. The nuclei of the cutis vera are increased in number. The upper border of the section represents the outer surface of the ear and the lower border the inner; placed nearly centrally the cartilage of the ear is seen. × 30.

On microscopic examination of the X rayed skin before the injection of Scharlach R (Figs. 2 and 4) it was found that a marked degree of destruction of the hair follicles had occurred. This was greatest in rabbit A (Fig. 2). The hair follicles remaining were diminished in diameter and in length, the former change affecting chiefly the deeper portion of the follicles, which were not unfrequently converted into thin cord-like structures. Most of the papillæ of the hair follicles had disappeared, and, as a rule, hair shafts were absent. In the upper part of the follicles a lumen was present containing epithelial scales, the accumulation of which sometimes caused distension of this part of the follicle. In the lower part of the follicle, in most cases, no lumen was recognisable and the follicle appeared to be solid, being made up of small prickle cells. The mouths of the hair follicles were observable as large openings, usually filled with loose horny epithelium. Sometimes the horny epidermis at, or just below, the mouths of the hair follicles had accumulated to such an extent as to give rise to epithelial collections reaching a millimetre or more in diameter. The sebaceous glands had in part disappeared. The hair follicles were more affected on the outer surface of the ear than on the inner. The surface epithelium shown in Fig. 2 is of about the normal thickness, but is pigmented to an excessive degree. The cutis vera, owing to the small size and number of hair follicles, is thinner than normal, and appears to be made up to a greater extent than usual of connective tissue. The blood-vessels are less numerous than usual; in consequence of this the cellular elements of the corium are fewer than usual.

FIG. 2.



Section of ear of rabbit A, exposed to the action of X rays 15 months previously. The portion of the ear represented lies close to that from which the previous section has been made, but is outside the area injected with Scharlach R. The hair follicles have been, for the most part, destroyed by the action of X rays. The surface epithelium is markedly pigmented, especially on the outer aspect of the ear. A large vein is seen above the cartilage, which does not extend completely through the section. This section should be compared with that given in Fig. 1. × 30.

In rabbit B (Fig. 4) the destruction of the hair follicles is less marked. It is little evident in the skin of the inner surface of the ear (lying below in the figure) in which the hair follicles mostly contain hair shafts of fair size, but in the outer skin of the ear the hair follicles are affected to a greater degree, fewer hair shafts being seen. The epithelial distension of the mouths of the hair follicles referred to above is exhibited in a marked degree. The surface epithelium differs from that in Fig. 2 in not being pigmented to an excessive degree. The number of cells in the corium is not diminished to the same extent as that in the previous animal.

The injection of Scharlach R into the skin of the rabbit's ear, exposed, as above described, to the action of X rays in an

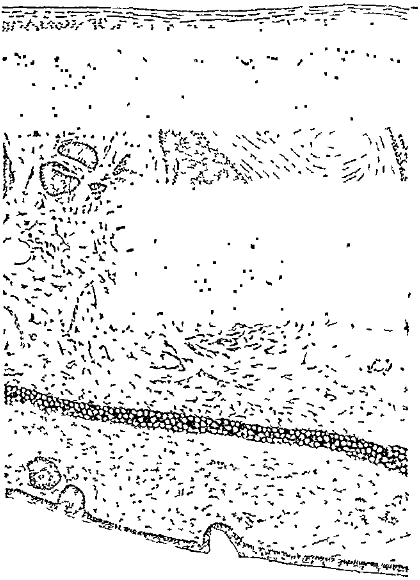
fol ... extreme degree of epithelial proliferation such as occurs in the normal epithelium of the rabbit's ear similarly injected ... increases in thickness at the ... of the horny layer takes place, ... ing on the surface At the en ... the ear may present a warty character, resembling that often exhibited by surface epithelium When the horny epidermal accumulations are removed a moist, irregular surface is exposed; complete removal of the epidermic scales is, however, difficult, for plugs may pass downwards into the proliferated prickle layer, portions of which may be torn off in the course of attempted removal of the horny epidermal accumulations

On microscopic examination of the section obtained from rabbit A (Fig. 1) it is seen that an extreme degree of proliferation of the rete Malpighii and of the prickle layer of the hair follicles has taken place, the proliferation being of two kinds: (1) a simple more or less regular increase in the number of epithelial cells; and (2) an irregular downgrowth or outgrowth of epithelium, produced under the influence of adjoining globules of oil containing Scharlach R in solution and strikingly resembling that seen in epithelioma The epithelial proliferation is marked on both sides of the central cartilage of the ear, but is more marked in the skin of the outer surface of the ear (upper surface in the figure) than in that covering the inner surface. The proliferation of the epithelial covering of the inner surface of the ear was caused by some of the solution of Scharlach R[4] injected into the connective ... the outer surface ... tissue covering ... rabbit B it will be seen that this did not occur) The enlargement of the lumen of the mouths of the hair follicles is obviously due to the very large general increase of the

FIG 3



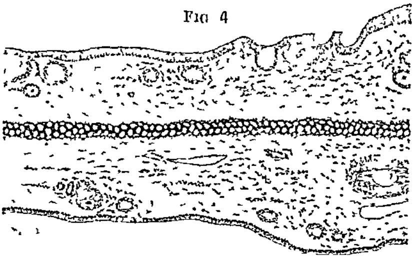
Section of the ear of rabbit B ...

In the lower part no marked change is observable × 30.

... from within due to an accumulation of horny scales, although such accumulation does occur to some extent. No hair shafts are seen in the section.

In the section obtained from rabbit B (Fig 3) the epidermal proliferation is confined to the skin covering the outer surface of the ear, the whole of the Scharlach R injected lying external to the cartilage of the ear, whereby its action was prevented from extending to the inner surface (lower surface in the figure) In this section marked increase of the epithelium of the surface and of the mouths of the hair follicles is observable One of the latter has undergone very considerable enlargement, the mode of origin of which will be understood on reference to Fig 4, taken from the adjoining part of the ear free from Scharlach R, which may therefore be taken to represent the condition of the ear before injection In the latter figure it will be observed that the empty mouths of the hair follicles are, as already mentioned, of large size, though the follicles themselves have become in part atrophied or destroyed The enlargement of the former, when it occurs, is therefore all the more striking In this section, as in that shown in Fig 1, a few sebaceous glands of small size can be recognised. It should be observed that injection of Scharlach R does not cause the appearance of proliferation in the cells of the sebaceous glands.

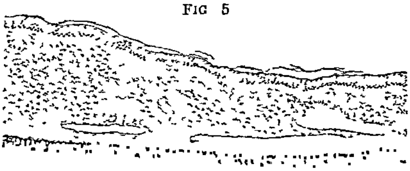
FIG 4



Section of ear of rabbit B exposed to the action of X rays 15 months previously The portion of the ear represented lies close to that from which the previous section has been made, but is outside the area injected with Scharlach R. The hai... case in ... is great ... cartilage ... pared w...

If Scharlach R is injected into the ear of a rabbit which has many months previously been subjected to severe X raying, then a result is obtained which differs in some respects from that above described If the skin of the ear has been sufficiently X rayed, all the appendages of the skin are destroyed, and the corium, which is sometimes thinner than normal, sometimes of somewhat increased thickness, containing a fair number of nuclei, is found to be made up

FIG 5



Section of ear of [illegible]

---

[4] Dissolved in olive oil.

of fibrous tissue covered externally by a uniform layer of epithelium, generally thicker than that observed in the normal condition (that is to say, 40μ to 50μ thick, the usual thickness being about 25μ). The condition of such X rayed skin is comparable to that of deeply scarred skin.

After the injection of a small amount of Scharlach R into such X rayed skin proliferation of the surface epithelial covering is observed to the extent represented in Fig. 5. In its character this epithelial increase is similar to the surface increase seen in Figs. 1 and 3. It does not, however, progress much further than is shown in Fig. 5, owing to the fact that the effect of the injection of more than a relatively small amount of Scharlach R is to cause necrosis. The fact brought out by the injection in such cases is, that Scharlach R, as would be expected from the results previously obtained, is still effective when its action is exerted exclusively upon skin exhibiting only surface epithelium, the appendages of the skin having completely disappeared.

FIG. 7.

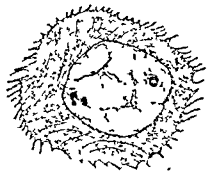


FIG. 8.

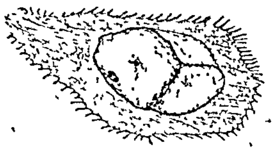

FIG. 6.

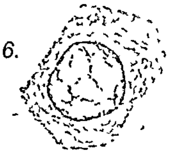

FIG. 9.

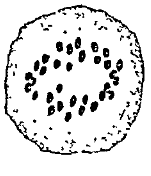

FIG. 6.—Normal prickle cell from Fig. 2. For comparison with the cell shown in the succeeding figure. × 1000.

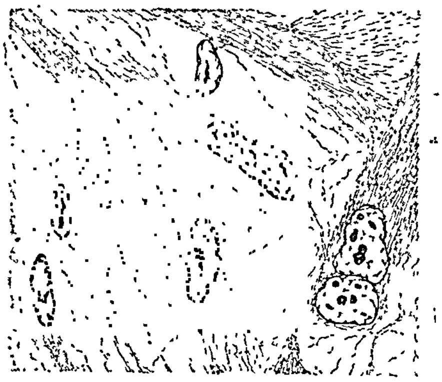
FIG. 7.—Pric[illegible] [illegible]elium shown in Fig. 1. Th[illegible] [illegible]oth nucleus and cytoplasm [illegible] [illegible]imensions. The prickles, w[illegible] [illegible] and drawn out, the prickle spaces being correspondingly increased in size. [illegible] [illegible]cations of the epidermal fibres [illegible]

F[illegible] [illegible] proliferated epithelium shown in Fig. 1, exhibiting fragmentation of the nucleus into three parts. × 1000.

FIG. 9.—Mitotic figure from the proliferated epithelium shown in Fig. 1. The chromosomes, more or less oval in form, are about 30 in number, and are arranged upon the equatorial plane of a spindle (not shown in the figure). × 1000.

The degree of X raying just described represents the limit available for experimental work, the stage beyond being that in which the surface epithelium is broken and sloughing may result. It is, however, difficult to carry out experimental work upon skin of the type shown in Fig. 5, even when the immediate effect of X raying has long passed off, for such skin remains in a condition of lowered vitality and is readily affected by injurious influences.

FIG. 10.



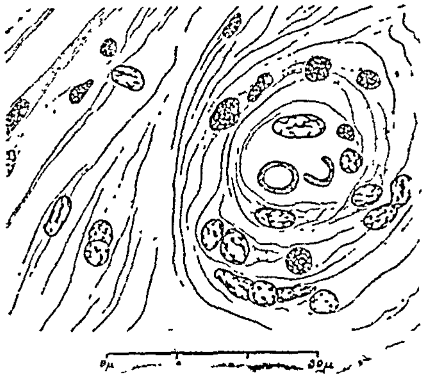
Portion of cutis vera of Fig. 3 more highly magnified Lying upon and among the connective tissue bundles (unstained) are numerous flattened cells, the cytoplasm of which is thin, lightly stained, and spread out upon the connective tissue fibres. × 650.

A marked feature of the action of Scharlach R upon the skin of the ear of the rabbit, subjected many months previously to the action of X rays, is its tendency to cause necrosis, even though the degree of X ray injury may not exceed that shown in Figs. 2 and 4. Blistering of the surface is readily produced, a crust forms, and the area of skin injected may pass slowly into a condition of dry gangrene. Should this occur a line of separation appears at the edges of the injected area, and ultimately the necrotic portion is shed, the ear showing a large hole when healing is complete. Suppuration does not occur, nor is any acute inflammatory process observable. The animal does not scratch the ear, and seems quite unconscious of the occurrence of any morbid process.

The tendency to sloughing is obviously related to the degree of destruction of the epithelial appendages of the ear. Even with slight degrees of X rays, the injection of large amounts of Scharlach R is likely to be followed by vesiculation, while in old X rayed ears in which severe changes have been produced it is difficult to avoid vesiculation, even though only a small amount of Scharlach R is injected. In consequence the opportunities of studying changes in the latter case are somewhat limited.

The characters of the changes in the proliferated epithelial cells following upon the injection of Scharlach R in old X rayed skin of the rabbit's ear are also similar to those following injection into normal skin. The proliferating cells of the prickle epidermis and of the hair follicles are increased in size, the increase affecting all parts of the cells. The nuclei generally measure about 12μ instead of about 9μ in normal prickle cells. (Figs. 6 and 7.) Fragmentation of the nuclei into two or more parts, not however always completely separated, is not uncommon. (Fig. 8.) The prickles are unusually distinct and the prickle spaces large. Indications of the epidermal fibres are more or less obtrusive. (Fig. 7.) Mitosis, which is fairly common, is characterised by the appearance of short oval chromosomes; these resemble those in the reduced division of epithelial cells already described.[5] In Fig. 9, which illustrates their appearance, about 30 chromosomes are present. I have not observed rod-like chromosomes in the sections made. In many of the mitoses the chromosomes were not sufficiently separated from one another to enable the type to be identified. The cells of the sebaceous glands disappeared after the injection of Scharlach R. No pigmented cells were visible, after injection, in the proliferated epithelium of rabbit A, though prior to injection of Scharlach R these were present in considerable numbers. (Compare Figs. 1 and 2.)

FIG. 11.



Portion of cutis vera of Fig. 3 more highly magnified. To the right a blood capillary is seen containing two red blood cells, in optical section. In addition to the endothelial nuclei and the nuclei of the connective tissue, which are lightly stained, several smaller darkly stained free nuclei are seen, chiefly disposed round the capillary vessel. The connective tissue is unstained, but the situation of the larger elastic fibres is partly indicated. × 500.

In the cutis vera, after the injection of Scharlach R into old X rayed skin, the connective tissue was found to be increased in amount (compare Figs. 1 and 2; also Figs. 3 and 4); the nuclei of the cutis vera were much more numerous than before injection. Among the latter large flat cells were obtrusive in rabbit B (Figs. 3 and 10), less so in rabbit A. These exhibited well-defined large nuclei and darkly stained cytoplasm forming thin prolongations, often branched, lying upon and between the connective tissue fibres (Fig 10) In addition to these, large nuclei, similar to the preceding, but not obviously flattened and not surrounded by any clearly defined cytoplasm were common among the connective tissue fibres and in the neighbourhood of the blood-vessels (Fig 11) Nevertheless, the number of free cells lying around the blood vessels was much less than had been observed when the healthy skin of the rabbit's ear was injected with Scharlach R Smaller nuclei, with relatively abundant chromatin, staining more darkly than the preceding (Fig 11), are also met with in considerable numbers lying between the connective tissue bundles and also around blood vessels, the cytoplasm of these nuclei could not be defined, multinuclear leucocytes were unfrequent The blood vessels of the cutis vera were diminished in number in proportion to the destructive effect of the X rays Some increase in the number of blood vessels, limited in degree, took place after injection of Scharlach R, the increase being greater the more vascular the skin was at the time of injection The liability of the X rayed skin to vesiculation and sloughing after the injection of Scharlach R is presumably related to the abnormal structural character of the cutis vera Mitoses of the somatic type are occasionally met with in the cells of connective tissue Mast cells are sometimes encountered, but pigment cells appear to be absent

---

[5] Loc. cit., p. 375.

Summary

1 In old X rayed skin of the rabbit's ear the injection of a solution of Scharlach R is followed by epithelial proliferation, which may reach an extreme degree, provided the destructive effect of the X radiation has not been excessive

2 A marked tendency to sloughing is observed when Scharlach R is injected into old X rayed tissues, the tendency being greater the more marked the extent to which the appendages of the skin have been destroyed

Medical Societies.

ROYAL SOCIETY OF MEDICINE

SECTION FOR THE STUDY OF DISEASE IN CHILDREN

Exhibition of Clinical Cases and Pathological Specimens

A MEETING of this section was held on Jan 24th, Mr A H TUBBY, the President being in the chair

Dr ANNE L J KANN showed for Mr DUNCAN C L FITZWILLIAMS a case of (?) Fibro lipoma It was that of a boy aged 2 years and 8 months On examination there were four small swellings, distinct from one another, on the back of the arm and in the axilla They felt fibrous, some being larger than others The axilla was filled with a mass about as large as an orange, which bulged forward the anterior axillary wall and appeared in front under the pectoral muscles It was firm, with well defined edges and slight lobulation It was moveable on the structures beneath and under the superficies There was no impulse on coughing or crying The child was very backward and undersized, with marked signs of rickets The fontanelle was still open

Dr ANNE KANN also showed for Mr FITZWILLIAMS a case of Lymphangioma resembling Hernia of the Lung It was that of a boy aged 6 The mother had noticed that something was wrong with the right side of his neck when he cried She stated th [illegible] was washing the child, [illegible] 12 months ago but she took little notice of it until it began [illegible] three months In November the [illegible] this lasted until the end of [illegible] his mother noticed that the lump got very large in his neck during the spasms of coughing On examination there was a fulness of the root of the neck above the right clavicle and behind the sterno mastoid muscle It was ill defined and quite soft, and small nodules could be felt in it It seemed to disappear under the fingers towards the region of the subclavian artery On coughing or straining the root of the neck filled up and bulged in a prominent manner, and on palpation the tumour again subsided Though breath sounds were heard they were probably transmitted The condition at first sight was extremely like a hernia of the apex of the right lung, but there was no indrawing on deep inspiration, nor could any ring be felt in the deep part of the neck The diagnosis was that the condition was an extensive lymphangioma with large loculi, the greater portion of the tumour being situated in the chest

Dr R C JEWESBURY showed cases of two similar but somewhat unusual heart conditions in sisters 1 Aged eight The mother was told by her doctor that this child's "heart was affected" when she was three weeks old. The child was not cyanosed at birth and had never been noticed to get blue She had suffered from dyspnœa on exertion for the last three to four years, and had complained of growing pains during the last two years There was no history of acute rheumatism The heart was enlarged, its apex beat being in the sixth space in the nipple line There was a systolic murmur at the apex conducted out The second sound was accentuated In the second and third left space a loud, rumbling murmur, partly presystolic and partly systolic, was heard, and a well marked thrill was felt in this position At the pulmonary area a systolic murmur was present conducted upwards to the neck Aortic sounds first sound soft, otherwise normal 2 Aged 10 years No heart disease was ever suspected until she was brought to hospital a few days before She had always been a healthy child There was no history of rheumatism, the heart was not enlarged In the second and third spaces a well marked systolic thrill was felt and over this area a prolonged, continuous, booming murmur was present, very similar to that heard in her sister s case

Mr R C ELMSLIE showed three cases of an unusual form of Disease of the Hip joint—"Calvé s Pseudocoxalgie" 1 A boy, aged 10 In November, 1909, he fell and twisted his right foot, and attended an out patient department for a week and recovered About three weeks later he was kicked on the right hip, which was noticed by the mother to be much bruised, from that time he limped and had occasional pain in the knee, especially after lying down He had no pain at night In the following March he came to the hospital At that time the hip movements were free except full hyper-extension, the limb was ⅜ in shorter than the left, the shortening being above the great trochanter, there was little wasting of the thigh A skiagram showed that the acetabulum was clear and smooth, but that the epiphysis of the head of the femur was a little flattened, its surface uneven, and its upper edge proportionately thicker than it should be, the neck of the femur appeared shorter and thicker than the normal He was kept in bed for three weeks, and the condition did not alter He was then allowed up A fresh skiagram taken in May showed no alteration After this he was kept under occasional observation until February, 1912 during which time the condition did not alter appreciably Subsequent skiagrams showed no important change although the flattening of the epiphysis and the thickening of its upper border became rather more evident 2 A boy aged 8 The parents in this case had not noticed anything wrong, but were informed after a school medical inspection that the boy limped He was brought to the hospital in January, 1912 At that time there was a little limitation of the abduction of the right hip joint most marked in the flexed position, other movements were free The shortening was very slight, not more than ¼ in, and there was a little wasting in the thigh A skiagram was taken, and the appearances were found practically identical with those in the last case The parents were then informed that no treatment would be necessary These two cases agreed as to clinical signs and skiagraphic appearances with Calve s description, but neither was observed in the acute stage described by that author The third case presented however some differences 3 A girl aged 9 At the beginning of 1912 this child had an attack of St Vitus s dance and rheumatism in the right leg In the summer she was an in patient for St Vitus s dance at a hospital She was transferred to a [illegible] ust While convalescent [illegible] noticed for the first time [illegible] pain or disability When she returned from a convalescent home the mother noticed the limp and brought her to St Bartholomew s Hospital in December No injury to the hip could be remembered The right hip was kept flexed, further flexion was free, extension was limited, abduction abolished, and rotation in both directions limited. The limb was ⅛ in. shorter than the left, this shortening being above the great trochanter. A skiagram showed the head of the femur to be deformed in much the same way as in the previous cases, but in addition the upper part of the acetabulum was eroded, and the head of the femur displaced a little upward; the femoral neck was short and thick. This case differed from the first two and from those described by Calvé in the changes in the acetabulum and in the partial upward dislocation.

Dr. J. WALTER CARR showed a case of Congenital Syphilis with enlargement of the liver and spleen. It was that of a girl aged 12. No definite family history of syphilis could be obtained, but the patient was the third child, and her mother had two miscarriages between the births of the second and third children. The girl was born at full term, and there was no evidence that she had any symptoms suggestive of syphilis during infancy. She was in hospital in March, 1911, for syphilitic disease of the soft palate, with pain and difficulty in swallowing. When shown, the uvula was destroyed and the remains of the soft palate were adherent to the posterior wall of the pharynx; there was a perforation on the left side of the palate communicating with the left nostril. The liver was much enlarged, reaching nearly to the umbilicus; it was hard, smooth, and not tender. The spleen was also enlarged and hard, extending about 3 inches below the costal margin. There was no albumin in the urine. There was a slight thickening of the middle third of the right tibia. The eyes were healthy. The report on the blood was as follows: Total red corpuscles, 3,750,000; total white corpuscles, 6500; polymorphonuclear neutrophiles, 61·8 per cent.; polymorphonuclear eosinophiles, none; mononuclears, large 18·7 per cent., small 19·4 per cent. Two nucleated red cells were seen in counting 350 white cells. Hæmoglobin, 100 per cent. Wassermann reaction strongly positive. Lately the child had got thinner and had complained of loss of appetite and diarrhœa.

Dr. CARR also showed a case of Hirschsprung's Disease in a boy aged 9. He was treated about six years ago for severe constipation. Since then he had always been more or less constipated, requiring a great deal of purgative medicine. He was admitted to hospital on Jan. 10th, and for six weeks previously his bowels had only been opened by injections. A number of very hard scybalous masses were felt in the hypogastric region; these had been removed by enemata, but there had been no spontaneous action of the bowels. The boy looked fairly healthy. The abdomen and the lower part of the chest were greatly enlarged, and the increased length between the ensiform cartilage and the umbilicus was very marked. The whole abdomen was very tympanitic, and there was marked visible peristalsis. The liver, spleen, and heart were all much displaced upwards, the heart's apex beat being in the third left space. The rectum appeared to be normal.

Dr. CHARLES W. CHAPMAN showed a case of Arteriosclerosis with absence of both radial pulses in a girl, aged 15. She was admitted to hospital on Nov. 20th, 1912. She complained of cough and orthopnœa on exertion or exposure to cold. There was rheumatism on the mother's side. No special illness until four years ago, when she suffered from loss of power in the legs, with loss of speech, the attack lasting 15 minutes. There were several similar attacks during the following six months. Bronchitis two years ago. She was said to have had chalky lumps on her abdomen last summer. When first seen the area of cardiac dulness was increased in both directions, that on the left side being 9 cm. beyond the mid-sternal line; the apex beat was in the sixth space at the extreme margin of the dulness. The finger-tips were slightly congested. Catamenia not commenced. Teeth very bad. On admission the cardiac dulness was as stated; the subclavians were visibly pulsating, and aortic pulsation could be felt by the finger in the aortic notch, the brachial and radial arteries were hard and devoid of pulsation, the iliac arteries were visibly pulsating, but only feeble pulsation could be felt at the left posterior tibial and not at all on the right; the apex beat was in the sixth space and the action cantering. The liver was enlarged. Urine: specific gravity, 1022; albumin, a trace; sugar absent; no casts or red blood cells. Wassermann negative. Since admission the child had gained weight and had generally improved; the cardiac dulness was diminished, and she could lie down in comfort. There was still a cloud of albumin. The skin on the abdomen was dusky, but no cyanosis or blanching was present.

Mr. SYDNEY STEPHENSON showed a case of Interstitial Keratitis and Osteo-periostitis of the Tibiæ treated with neo-salvarsan. It was that of a boy aged 6. Ten years ago the mother was affected with some nasal trouble, for which she was treated. One child, born prematurely at the seventh month, died when aged 7 weeks from some cause unknown to the mother. There had been no miscarriages or stillbirths. Nine or ten months ago the patient was said to have suffered from "rheumatic pains" in the backs of the hands, shoulders, both knees, and both legs. Just before last Christmas the father noticed a film over the child's right eye, and then found that he could only tell day from night with the affected eye. The patient was admitted to hospital on Jan. 9th last. When admitted he showed no signs of syphilis as regards his face, cranium, or teeth. The inguinal and cervical glands were slightly enlarged and "shotty" to the touch. The skin was in a state of xeroderma. Nodes were present on the middle third of each tibia, being more marked on the right side. The overlying skin was not discoloured, and the swellings themselves were not tender. There appeared to be the remains of a similar node about the middle of the right ulna. The Wassermann reaction was positive. In the right eye there was a trifling ciliary redness and photophobia. The pupillary area of the cornea showed a disc-like interstitial opacity, while the peripheral parts of the cornea were almost clear. The anterior epithelium covering the opacity looked as if it had been breathed upon. The pupil, although the eye was being treated with atropine (2 gr. to the ounce, three times a day), was no larger than 4 mm. It was probably fastened down by posterior synechiæ. Tension normal. Vision, perception of light. On Jan. 20th, 1913, neo-salvarsan, 0·6 grm., was injected intravenously with beneficial effect.

Dr. J. D. ROLLESTON showed specimens of Congenital Renal and Ureteral Anomaly. It occurred in a boy aged 12. Death took place from generalised paralysis, following very severe faucial and nasal diphtheria, on the forty-seventh day of the disease. There were violent attacks of abdominal pain during the last 24 hours of life. Albumin was present in the urine from the third to the thirty-eighth day. The first specimen showed (1) solitary or asymmetrical left kidney, 4¾ in. long, 2 in. broad, 1¾ in. thick, 6 oz. in weight; (2) duplication of ureter, the upper branch, 4 in. long, supplying the upper third, and lower branch, 3½ in. long, supplying the lower two-thirds of the kidney. The second specimen showed union of the two branches of the left ureter 3 in. from the bladder, the left ureteral orifice in the bladder, and a right ureter which was pervious from the bladder to its blind upper extremity. The right kidney, renal artery and vein, and right suprarenal were absent.

Dr. G. A. SUTHERLAND and Mr. H. W. PERKINS showed a specimen of Non-development of Cerebrum. The case was that of a female child aged 9 weeks. The head resembled that of a normally developed infant of this age, the circumference being 13⅛ in. The anterior fontanelle was widely open, measuring 2 in. in the sagittal direction and 1 in. in the coronal. The sutures were not united. On opening the skull a quantity of blood-stained fluid escaped, amounting to 9 oz. On centrifuging this the blood cells were thrown down, leaving a clear supernatant fluid of a straw colour. The dura mater appeared to be normal and the falx cerebri was fully developed and present throughout its whole length. The hæmorrhagic fluid present was apparently in the cavity of the arachnoid. This cavity was partially divided in the occipital region by a few fine, cobweb-like adhesions, present chiefly on the left side. The brain, lying on the base of the skull, was very small and covered with thickened, œdematous-looking pia-arachnoid, which concealed its outline. On the removal of this membrane it was seen that the brain was extremely ill-developed as regards the cerebral lobes. The brain weighed 80 grm. Each cerebral hemisphere measured 9 cm. in length, 6 cm. in width, and 3·7 cm. in depth, taking the maximum measurements. The two halves of the dwarfed cerebrum on each side of the falx cerebri were roughly symmetrical, except that posteriorly into the occipital lobe on the left side a large hæmorrhage had taken place, the clot being recent and unorganised. The middle third of the cerebral cortex on each side presented numerous convolutions, which, although small and narrow, were separated by well defined sulci The anterior parts of the cortex were extremely thinned and so intimately associated with the pia arachnoid that it was difficult to recognise any well marked convolutions or sulci The appearance here was that of numerous small cavities, like a honey comb, bounded externally by the thinned cortex and pia arachnoid Definite convolutions and sulci were present at the posterior pole on the right side, whilst on the left side the posterior pole was the seat of the extensive hæmorrhage referred to above This hæmorrhage formed a roughly spherical clot about 25 mm in diameter, limited externally by the thinned out cortex and pia mater, and suggesting from its appearance the possibility of its having arisen from bleeding into a thin walled cyst The basal surface of the cerebral lobes presented a crinkled appearance, well defined convolutions and sulci being absent The cerebellum, medulla, pons, and peduncles presented a normal appearance All the cranial nerves could be identified, and the blood supply and blood vessels were normal so far as could be determined A transverse section through the right cerebral lobe at the level of the corpus callosum showed that the lateral ventricle was slightly distended, and that the ependyma and choroid plexus were normal The brain substance beneath the ependyma had a spongy, reticulated appearance, and in the floor of the ventricle, beneath the lining membrane, was a small cavity about the size of a pea filled with blood clot The left ventricle was but slightly enlarged The foramen of Monro was patent and normal The third and fourth ventricles were not enlarged, and the patency of the "iter" was established The cortex of the mesial aspect of the cerebrum, when cut into, showed numerous small spaces about the size of a hemp seed The baby was shown at the November meeting of the section

Dr HUGH THURSFIELD and Mr H W SCOTT read a paper on a case of Sub aortic Stenosis

Dr F G CROOKSHANK read a paper on Mongolism

SECTION OF ANÆSTHETICS

Use of Nitrous Oxide and Oxygen in Major Surgery

A MEETING of this section was held on Feb 7th, Dr J BLUMFELD the President being in the chair

Mr H M PAGE read a paper on the use of Nitrous Oxide and Oxygen in Major Surgery A revival in recent years of the interest taken in anæsthesia was attributed to Dr Crile's work on shock The recent work done in America was

e paper being to suggest

gents on this side The

the surgeon was not to be hindered in his work, the strain on the anæsthetist, the cumbrous apparatus and expense were pointed out Against these drawbacks were placed the non toxicity of N_2O the few after effects, and the good condition of the patient at the end of the operation when compared with the other general anæsthetics It was maintained that this favourable condition was found to exist in a proportionately *modified degree even when ether had been added all the time* Regulated rebreathing was strongly advocated Mr Page having found that his patients were none the worse for it, and the administration facilitated The work of the physiologists on the subject of the loss of CO_2 and acapnia was mentioned, and especially the recent work of Yandell Henderson, and it was maintained that account must be taken of it and rebreathing carefully used even if all Henderson's conclusions were not ultimately agreed to Ninety four major operations were brought forward, 51 having been intraperitoneal operations The ages of the patients varied from 5 to 81 years Seven out of these 51 intraperitoneal cases died All of these were desperate cases which were being given the last chance They died a few hours or days after the operation None died immediately The special indications for the method were said to be 1 Desperate cases from toxæmia or traumatism or hæmorrhage, if spinal anæsthesia was not used 2 For operations on *diabetics* It was *to be pre*ferred to spinal anæsthesia or any general anæsthetic 3 In certain genito urinary operations A previous injection of a narcotic with atropine was recommended and failing this atropine alone Induction was recommended to be always done with the addition of ether, and afterwards to return to the addition of ether to get the depth of anæsthesia required rather than to push the N_2O by increasing pressure It was stated that a tendency to cessation of respiration without toxicity and possibly due to loss of CO_2 might be met with and also a true toxicity The most important contra indications were advanced degeneration of the heart and vessels, a marked degree of emphysema and dyspnœa, or obstruction to the air way Deaths said to be due to the anæsthetic had been *reported* Mr Page's opinion was that these dangers and deaths could be avoided by the unremitting attention of a skilled anæsthetist who had seen his case beforehand and deliberately chosen this method, and that $N_2O + O_2$ with or without the addition of ether would then give the patient in certain cases an additional chance of recovery Mr Page then gave a demonstration of Dr Teter's apparatus, recommending that a bag should be added close to the face piece, also

gether which

ansr

tated that all

app

The PRESIDENT considered that Mr Page had made out a good case for the use of gas and oxygen, and for rebreathing, at least in very dangerous cases He had himself in a few cases used gas and oxygen where it was essential to avoid any toxic effects, and in those his experience agreed with that of Mr Page It was difficult to reconcile the avoidance of the asphyxial element with the view that no diminution must be allowed in the CO_2 content of the blood

Mr H BELLAMY GARDNER said that in 1897 he brought forward the use of gas and oxygen for minor operations—i e, those not involving abdominal section, and in the following year Mr Herbert Paterson used it for a case in an operation lasting 1 hour and 55 minutes Later he (Mr Gardiner) related his experiences with it for larger operations but still excepting abdominal sections It was many times more expensive than the older general anæsthetics, but was particularly indicated for diabetics, in which case it was the most valuable anæsthetic available

Dr H DES VŒUX spoke highly of the anæsthetic in some of his patients whose condition demanded the greatest possible care, and testified to the rapid recovery of consciousness and the lack of unpleasant after effects

Mr H E G BOYLE asked Mr Page as to the relaxation of abdominal muscles when gas and oxygen was the anæsthetic When no other narcotic was given beforehand and no ether added to the gas and oxygen, he found it difficult *to procure such relaxation, but no doubt* it was easier to procure if these additions were made to the gas and oxygen He agreed that it was the best anæsthetic for diabetics, and had given it in three such cases with success for amputations at or about the knee He did not advise it for rectal operations because of the spasm and opisthotonos that occurred

Mr C J LOOSELY had used the apparatus (Dr Teter's) in six cases, all children, with success In one case however, he had to use a *little ether to keep up the relaxation of the* muscles

Mr ASLETT BALDWIN had the highest opinion of this anæsthetic for major surgery, especially when the patient was already partly poisoned by diabetes or sepsis For rectal work he got over the difficulty of the opisthotonos by placing the patient on his side and trussing him up with a *jack towel*

Dr A L FLEMMING (Bristol) exhibited a simplified *apparatus of* his own design and manufacture for giving gas and oxygen, which allowed of rebreathing

Mr PAGE replied

SECTION OF OPHTHALMOLOGY

Exhibition of Cases —The Physiology of Intraocular Pressure

A MEETING of this section was held on Feb 5th Sir ANDERSON CRITCHETT, the President, being in the chair

Mr G COATS showed a case of Congenital Mesoblastic Strand adhering to and penetrating the Cornea He *suggested* that *if in early fœtal life* the amniotic fluid was not sufficiently developed or was too scanty, the amnion might come into contact with eyes which were prominent at the time, and might acquire adhesion to the developing eye

Dr A RUGG GUNN showed a case of Persistent Hyaloid Artery with massive white *formation obscuring the optic disc.*

remarks on the anatomy of the joint, illustrated by lantern slides, Mr. Finch considered the mechanism of the joint. He showed that theoretically a sudden extension from a flexed or semi-flexed position would cause injury to the internal semilunar cartilage. This was confirmed by a definite history of a sudden extension in 44 of the 59 cases. In 7, however, the patient declared that the joint was fully flexed, and in 8 the position could not be ascertained. He briefly considered the symptoms and signs, pointing out that the diagnosis, when the patient came to hospital, was usually based on the history of the accident and the subsequent history of the patient as regards locking of the joint, &c. 25 of the cases were miners who had been injured in the pit; 20 of these had the joint injured by a sudden extension movement. The treatment recommended was operative, and by that he meant removal of as much of the cartilage as possible. In 3 cases where the cartilage had simply been stitched down it had to be removed subsequently. The after-treatment was to let the patient walk as soon as possible with no retentive apparatus on the limb whatever. The cases in which there was any ankylosis had all worn hinge splints subsequent to operation. Of the cases, 56 had injury to the internal cartilage and 3 to the external. Two cases had both cartilages removed from the same joint. The ages ranged from 11 to 56 years. The average duration in hospital was 22 days, the least 7 days, and the longest 37 days. The length of time elapsing after the operation before work was resumed was from 9 days to 5 years. Five had not resumed work, and of these one had marked fibrous ankylosis. In the other four no satisfactory cause could be found for the alleged incapacity. In 10 cases 9 months or more elapsed before work was resumed. In the remaining 44 cases the average time was 4 weeks. In the great majority of the cases creaking was felt in the joint on movement, but in no way interfered with their work. There had been no suppuration. The technique he left for discussion by the members of the society.

Mr. FINCH also showed a specimen of Osteomyelitis and Periostitis of the Right Tibia, removed by amputation from a youth of 16. The specimen showed an involucrum containing sequestra and cloacæ. The supposed cause was a "twist of the ankle" six weeks before admission to the infirmary.

Mr. GRAHAM S. SIMPSON, in a paper on Stone in the Kidney, based his remarks on an analysis of 30 operations for stone; of these, 16 were in the kidney; 4 were in the ureter; there was 1 case of hydronephrosis from stone, and 9 cases of calculous pyonephrosis. Under the heading of the examination, he stated albuminuria was present in 24 of the cases, that obvious hæmaturia was noticed in only 10, that skiagraphy was positive in 20 out of 21 cases, and that cystoscopy was useful in confirming the side of the lesion in 15 out of 19 cases. As regards treatment, he was an adherent of pyelotomy for removing stones, the great advantage being that there was no hæmaturia after the operation in these cases. No case of urinary fistula occurred in this series. Of the ureterotomies two were done by the extra-peritoneal route, one by the transvesical route and one by the intra-peritoneal route. The latter he regarded as an excellent operation. Nephrectomy was done nine times, once for a small contracted kidney full of stones and eight times for pyonephrosis. Only one case died. In this man a nephrotomy was done for multiple stones, and the patient died suddenly on the seventh day, apparently from a pulmonary embolism.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 31st, Dr. A. Freeland Fergus, the President, being in the chair.—Dr. A. Ernest Maylard showed several cases of Cancer of the Colon treated by operation to illustrate abdominal incisions and methods of intestinal anastomosis. The incisions recommended were: (*a*) for exploration, the seat of obstruction in the colon being uncertain—a mid, sub-umbilical vertical incision; (*b*) for cæcum and lower ascending colon—an oblique incision in the right iliac region; (*c*) for hepatic flexure and upper ascending colon—a transverse incision carried outwards from a point situated above and to the right of the umbilicus; (*d*) for transverse colon—an incision carried across the abdomen 1 to 2 inches above the umbilicus; (*e*) for splenic flexure and upper descending colon—a transverse incision carried outwards from a point situated above and to the left of the umbilicus; incisions (*c*) and (*e*) gave access also to kidney tumours; (*f*) for lower descending, iliac, and pelvic colon—an oblique incision in the left iliac region. The methods of intestinal anastomosis illustrated were: (1) by lateral approximation; (2) by lateral implantation or side-to-side union; and (3) by invagination—i.e., pulling a short length of the proximal segment through a longitudinal opening in the wall of the distal. The method to be adopted in any case was determined by the amount of free gut available after removal of the involved segment. Where this was limited the first, where less limited the second, or preferably the third, method was recommended. This last lessened the tendency to leakage in the event of distension of the bowel, and diminished the grave risk of infection at the mesenteric attachment. To prevent distension after operation it was advised that the sphincter ani be paralysed and a rubber tube of large calibre inserted, encircled with iodoform gauze soaked in glycerine. Through this gas could escape freely and any discharges which might result from the irritative effects of the bowel wound.—Dr. Crawford Renton read a short paper on Obstruction of the Bowels. He referred to the various causes of obstruction and recommended the sigmoidoscope as an aid to the diagnosis of tumours in the rectum and sigmoid. In very acute obstruction Paul's or Moynihan's tube was advised to drain the bowel previous to a radical operation. The adoption of this procedure had greatly reduced the mortality. Where cæcostomy had to be done the method recommended by Kader for the stomach had been found useful. For paralysis of the bowel eserine salicylate and pituitary gland were strongly recommended. In the last 33 cases which Dr. Renton had operated on there were three deaths, which was encouraging, and if the operations were carried out early in every case the mortality ought to be less.—Dr. W. Watson read a paper on the Adulteration of Foodstuffs and its Influence on Digestion. The 1901 report of the Local Government Board upon the use of preservatives and colouring matters in the preservation and colouring of food showed that the substances most commonly used were boric acid, borax, salicylic acid, formalin, and sulphites, while a large number of other substances were in less common use. One or other of these was found in 39 per cent. of all samples of food examined, including samples of milk, cream, butter, margarine, sausage, bacon, brawn, potted meat, potted fish, meat extracts, meat juices, and temperance drinks. All these preservatives were germicides, all were gastro-intestinal irritants, and all had a more or less inhibitory action on the gastro-intestinal ferments.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on Feb. 7th, Mr. Henry Curtis, the President, being in the chair.—Dr. W. Langdon Brown read a paper on Modern Methods of Diagnosis in Certain Digestive Diseases. Dealing first with the referred tenderness in abdominal disease he showed that the combination of superficial hyperæsthesia over the tenth thoracic segmental area, which includes the umbilicus, with deep-seated epigastric tenderness, was very suggestive of gastric ulceration. Hyperæsthesia in the region of the gall-bladder and appendix should be looked for in all cases of acid dyspepsia, as this might lead to detection of the origin of the trouble. The cutaneous areas of hyperæsthesia were not altered by displacement of the viscera. He then showed a series of skiagrams to illustrate the appearances of the normal stomach and the changes produced by malignant disease, gastroptosis, gastrectasis, perigastric adhesions, spasmodic contraction due to ulcer and the hour-glass stomach, pointing out the great help in diagnosis afforded in this way. The subject of the test-meal was then taken up and the methods of qualitative and quantitative analysis demonstrated. The value of determining the total acidity was shown by reference to the conditions in which the acidity was lowered (acute and chronic gastritis, achylia gastrica, and malignant disease) and those in which it was increased (simple hyperchlorhydria, peptic ulcer, cholelithiasis, appendicitis, and colitis). His opinion was that in such conditions as cholelithiasis and appendicitis the symptoms of acid dyspepsia were apt to be more definite than the test-meal findings. High acidity of the vomit was suggestive of simple pyloric obstruction. The method of examining the stools for occult blood by the benzidene test was demonstrated and its importance in the recognition of ulceration or malignant disease of the alimentary tract insisted on. Continuous small losses were suggestive of cancer, while intermittent larger losses pointed to a peptic ulcer.

Reviews and Notices of Books.

An Introduction to the Study of the Protozoa with Special Reference to the Parasitic Forms By E A MINCHIN, F R S London Edward Arnold 1912 Pp 520 Price 21*s* net

THIS compact volume contains all the main facts with reference to the structure and classification of the protozoa, although it is described by the author as simply an "introduction" There is probably no group of animals in which recent progress has so largely increased the bounds of knowledge as in the organisms of which Professor Minchin treats Thus the problem before him was clearly not how to spin out his work, but how to concentrate and what to leave out This has been partly accomplished by reducing the discussion of dubious questions and by adopting deliberately a "didactic attitude," which is perfectly legitimate in so well informed a student of the group, especially when it is duly advertised in the preface, so that no misunderstanding can occur The huge bibliography of the protozoa is also reduced to a little less than 30 pages, which will seem to the student not so well acquainted with the group a pretty fair list of publications, but Professor Minchin states that such a bibliography, if full, would easily occupy a volume by itself as large as that which now claims our attention By these and other economical methods a comprehensive, but not unwieldy, treatise has been produced, which should furnish the serious student with all that he wants

The book is divided into two parts of approximately equal size The commencement is a general account of the protozoa as a whole, and treats of their anatomy, reproduction, and physiology It is this part which will be most generally read The second half of the volume which is rather the larger, is systematic, and treats of these organisms in order of classification Finally a very few pages serve for the discussion of certain doubtful forms—particularly the spirochætæ—whose position in the system is still hotly debated and not decided. To make of a treatise of this kind a reliable guide to the student it is plain that the newer work by frequently very young writers should receive a due share of attention Here Professor Minchin has not been found wanting, some of his quotations extending even to the year of publication of his "Introduction" As a matter of fact, a quite great amount of the researches carried out among the protozoa is very new This is owing not to the greater efficiency of newer workers as compared with their forerunners, but rather to the discovery of histological methods which render clear structures previously invisible to the older authors The remarkable fact is not how little was known before the last decade or so, but how much the writers of comparative antiquity were able to ascertain with their inferior technique We find, therefore, some references in the bibliography to such writers, but it must be confessed that the vast majority of the entries are of the present century

As would be expected from the title the most copious bibliography relating to any one group refers to trypanosoma and its very immediate allies, it is no less than four pages long It is not unreasonable on the part of the author to devote very marked attention to these and other forms so directly interesting to men on account of their connexion with disease, and Professor Minchin's own work upon the protozoa is almost exclusively in this direction A glance at the bibliography shows a comparative neglect of the non parasitic forms of protozoa, such as the foraminifera and other groups, for which we are prepared by the author's declared limitations of his subject, but which is perhaps to be deprecated if only on the grounds that we must seek in free living forms for the origin of the parasites so fully treated of here Indeed, the expression "protozoology" so commonly used at the present day hardly implies more than the study of trypanosomes and hæmosporidia We must not be understood as in any way withholding admiration for, and appreciation of, the important discoveries of recent years upon the protozoan parasites of the blood, but as simply entering a plea for the less exclusively utilitarian views which are now so little in vogue

---

Experimental Physiology By E A SCHAFER F R S, Professor of Physiology in Edinburgh With 83 illustrations London Longmans, Green, and Co 1912 Pp 112 Price 4*s* 6*d* net

THE present volume is based upon "Directions for Class Work in Practical Physiology" published by the author just over a decade ago The matter treated of in that volume is reinforced by additions chiefly dealing with experiments on the circulatory, respiratory, secretory, and nervous systems, having regard to such experiments as may be performed by the student either in class or individually in this country The work is intended for elementary and advanced students but the author does not discriminate between the experiments which are expected to be performed by one or the other grade

The work consists of 30 chapters In Chapter I, under ciliary motion, it might be well to indicate that the epithelium should be scraped from the roof of the mouth of a frog in which the brain has been destroyed Instructions are given on the electrical apparatus commonly employed in physiology, and simple experiments are supplied to illustrate their use The next chapters deal with the nerve muscle preparation, nerveless muscle, recording of a simple twitch and the usual experiments on the work, extensibility and fatigue of muscle, the excitation of muscle and nerve by galvanic stimulus, conduction in nerve, electrotonus electrical conditions of nerve and muscle, and a few experiments on involuntary muscle These subjects occupy somewhat more than half of the text

The frog's heart and the leading experiments on this organ, including perfusion experiments and experiments on the cardiac nerves of this animal, are next described Then follow chapters on the structure and action of the mammalian heart, the blood vessels, blood pressure and the pulse, and perfusion of vessels and lymph hearts, which bring the experiments on the circulation to a close To the mechanism of secretion one chapter—two pages of small print—is given, to include the description of typical experiments on the submaxillary gland, pancreas, mamma and kidney Four pages are allotted to respiration, and short accounts of experiments on nerve roots, reflex action and reaction time are followed by the easily performed experiments on cutaneous gustatory and olfactory sensations and directions for experiments on the dioptric mechanism of the eye and stimulation of the retina A couple of pages are devoted to the production of vocal sound, audition, and the semicircular canals

It will be seen that the author covers the ground required by a medical student to enable him to profit by the instruction offered in his clinical work The directions are definite clear, and precise the experiments well selected, while the illustrations are numerous and are drawn in a bold and striking manner which catches the eye and makes them a marked feature of the book They refer chiefly to instruments and arrangements of apparatus, tracings obtained being practically excluded The work is a concise and excellent presentation of the subject with which it deals

There is a list of contents but no index. For one not familiar with the fixing of tracings it might be well to state the composition of the varnish used.

Diseases of the Nervous System. By JUDSON S. BURY, M.D. Lond., F.R.C.P. Lond., B.Sc. Vict., Senior Physician to the Manchester Royal Infirmary, and Professor of Clinical Medicine in the University of Manchester. Manchester: The University Press. 1912. Pp. 778. Price 15*s*. net.

Dr. Judson Bury's text-book on diseases of the nervous system is written in an essentially modern spirit, and in it are embodied the most recent investigations in the realm of neurology. With over 200 photographs and diagrams by way of illustration, pleasantly written and well printed, the work should find an assured place in English medical literature.

The author's classification of his subject is avowedly clinical, and on the whole we do not think it could be improved on. Clinical grouping of cases and of diseases is the most satisfactory from the teaching point of view, so long at least as their pathology in not a few instances remains obscure. Further, the student commences his exploration of neurology from the clinical side as a rule, and we agree with the author that the correlation of clinical types with the corresponding neuronic lesions is the best way of starting the student on a study from which he is apt, it may be, to be repelled unless he can, as it were, see light from the beginning. Thus the regional diagnosis of nervous diseases and the grouping of clinical symptom-complexes, considered together, will ere long enable him to attain those refinements in diagnosis which are the mark of the expert. We must, further, express our gratification at the bold way in which Dr. Bury has declared his intention of avoiding the terms "organic" and "functional." Nothing could possibly be more misleading, we contend, than the indiscriminate use of the term "functional," especially when regarded as identical with "hysterical." There must be no difference in the student's investigation of these two groups of diseases, even if we assume that they can be differentiated. As a matter of fact, the attempt would be both unwise and reactionary; all nervous disease must reveal itself by impairment of function, and all symptoms in this sense are "functional." Dr. Bury sagely observes that the adoption of this mental attitude by the student will lessen the likelihood of his overlooking the beginnings of serious changes in the nervous system, which may have led to the manifestation of some of the phenomena loosely described as "functional.'

In Dr. Bury's classification we question whether it is expedient to separate clinically "intrinsic diseases of the spinal cord" (Chapter VI.), including myelitis, intramedullary tumours, syringomyelia, spinal hæmorrhage, and compressed-air sickness, from "spinal disorders characterised by the presence of pain" (Chapter VII.), including diseases of the spinal membranes and diseases giving rise to compression of the spinal cord. The assumption would be that the diseases of the former group are not painful, but this can scarcely be maintained in view of the fact that in caisson disease the almost pathognomonic symptom is the well-known "bends" or pains, while intramedullary tumours may certainly, though occasionally, give rise to severe root pains, and, on the other hand, compression of the cord from whatever cause need not be, and is not always, accompanied by pain. In mentioning the common pathological changes in the cerebro-spinal fluid a note might be added on the occurrence of spontaneous coagulation and of a xanthochroic change in various cases of complete spinal compression where circulation of the fluid is interfered with. Dr. Bury states that the order of involvement of cranial nerves in extra-cerebellar tumours is eighth, seventh, sixth, respectively. It is not uncommon, however, to find that after the eighth the sensory fifth is next involved. In the section on infantile cerebral hemiplegia we note that the superficial reflexes are described as generally diminished on the hemiplegic side; it is a curious fact, in this connexion, that in a considerable proportion of cases, for an unknown reason, the abdominal reflex is lively on the affected side.

Dr. Bury's text-book can be put with every confidence into the hands of the student of neurology. For the work bears every evidence of original thought as well as of a widely cultured interest in modern neurological literature; it is thoroughly practical, readable, and accurate, and we congratulate the school of Manchester, wherein the work necessary for its production has been done.

Pathologische Anatomie des Ohres. Von RUDOLF PANSE, Dresden. Mit 208 zeichnungen des Verfassers nach eigenen prepäraten und 4 schemas. Leipzig: F. C. W. Vogel. 1912. Pp. 239. Price, paper, 12 marks; bound, 13.50 marks.

THE publication of a large book devoted entirely to the pathological anatomy of the ear might at first sight appear an ultra-refinement of specialism. A little consideration, however, will show this not to be the case, for nowhere else in the body is there an organ enclosed in dense bone; nowhere else is such special technique required in the investigation not only of abnormal, but even of normal, conditions. Again, difficult of investigation as are the intra-labyrinthine abnormalities and diseases, they have but a modicum of interest to those engaged in the study or practice of medicine, excluding aurists. The result is, that were it not for special treatment, aural pathology would not attract the attention it requires and deserves. The technique is handled clearly and at the same time very briefly, but enough is said in regard to fixing, decalcification, staining, and so forth, after which each part of the aural appendage is investigated from the external ear to the brain. It is, however, chiefly, if not entirely, in the pathological states of the labyrinth that the interest of the book lies, and that without detracting from the merits of the remainder.

For the student of aural disease Professor Panse's book will be quite valuable. As a trustworthy guide and book of reference it is to be heartily recommended, though it is a pity that, like that of so many of his compatriots, his reading appears to be confined exclusively to the writings of his fellow countrymen.

Diseases of the Skin. By WILLMOTT EVANS, M.D. Lond., F.R.C.S. Eng., Surgeon to the Royal Free Hospital and to the Skin Department of the Royal Free Hospital, and Senior Surgeon to the Hospital for Diseases of the Skin. Blackfriars. With 32 illustrations. London: Henry Frowde and Hodder and Stoughton. 1912. Pp. 375. Price 10*s*. 6*d*. net.

IN his preface to this manual Mr. Evans states that it is intended to provide an introduction to the study of diseases of the skin, the standard treatises on the subject being too advanced for those who are beginners. Within the past decade there has been a great increase of attention devoted to dermatology both by students and by general practitioners. Coincidently, therefore, there has arisen a demand for works dealing with dermatology in a less exhaustive manner than is required by the specialist in that subject. To meet this growing need quite a number of short volumes on skin diseases have been published within recent years, and amongst them may worthily rank the text-book under review.

Mr. Evans has arranged the subject matter very usefully, and the brief, yet clear and systematic, account of each disease is admirably adapted to suit the needs of the student Recondite theories and lengthy pathological details are avoided Moreover, the reader of dermatological works is usually bewildered by the large number of remedies recommended in the treatment of skin diseases Mr Evans wisely limits his paragraphs on treatment to one or two prescriptions which he has personally tested and approved

We regret to see that seborrhœa is discussed under the old divisions—seborrhœa sicca and oleosa—introduced by Hebra The recent work of Sabouraud has thrown a flood of light on the causation of seborrhœa and the allied conditions so long confused with it Syphilis is, perhaps, as completely described as is necessary considering the scope of the book, but in a future edition it would, we think, be an advantage to enlarge the paragraphs on diagnosis and treatment This protean disease imitates so many other skin diseases that not only the student but also the dermatologist is frequently puzzled in his endeavour to distinguish it from the clinical appearances of pityriasis rosea, psoriasis, and lupus vulgaris Mr Evans does not enumerate all the points which might be passed in review before a diagnosis can be hazarded in obscure cases where the Wassermann test cannot be applied, indeed, throughout the book the paragraphs on diagnosis of the common diseases could with advantage be extended We find no mention of sporotrichosis or of pseudo pelade, although some even rarer diseases are fully dealt with

The illustrations and the coloured plate are quite up to the standard expected in a modern work on dermatology, and we consider that this manual will prove very useful for the purpose for which it is intended—it will greatly lighten the work of the student by its clearness and simplicity

---

Health and Medical Inspection of School Children By WALTER S CORNELL, M D London Stanley Phillips 23, Creighton road Queen s Park, N W , Philadelphia F A Davis Co 1912 Pp 614 Price 12*s* 6*d*

DR Walter S Cornell s book consists of two main divisions the first comprising medical inspection and hygiene and the second a consideration of the defects and diseases of school children in detail In the first or administrative, section we note some interesting differences between American and English practice The United States system is not so definitely organised as is our plan of inspection over here, and a study of the method of work and forms used in this country, and of the relation of our Board of Education to the local authorities, would well repay American administrators On the side of administration the American methods are somewhat primitive, but the lack of centralisation allows of an interesting variety of experiment, and there are many useful hints to be got on this side of the work A daily visit to the schools to see ' special" cases seems usual, routine weighing and measuring are discarded , and unvaccinated children are excluded until they have been vaccinated owing apparently to a much greater frequency of local epidemics

The method of examination of children is much the same as in Great Britain, but as the inspector has no authority to examine the chest, and as the parents are not usually summoned to be present at the time of examination (nor, by the way, are teachers) there is no effective record of chest troubles of spinal curvature or of those heart defects found to be so common at inspections in this country Undressing and examination for "general cleanliness" is classified as "work which is scientific but impracticable of accomplishment ' Twenty children is the number suggested for examination on one day by each inspector Dealing with treatment of defects, we find the same pressure in America as in England toward the provision of treatment by public authorities and in some cities such treatment is now provided Dr Cornell lays it down that each city should retain in its service for treatment and diagnosis, a neurologist, a dermatologist an ophthalmologist and an orthopædist

The administrative suggestions are interesting, and the larger part of the work relating to the special defects dealt with by the school doctor will prove valuable and helpful to all engaged in actual inspection of school children Much space is devoted to the consideration of eyestrain and of mental deficiency The book is well illustrated, and can be cordially recommended to all school hygienists as a useful survey of the clinical conditions to be expected

---

The National Insurance Act, 1911 Being a Treatise on the Scheme of National Health Insurance and Insurance against Unemployment Created by that Act with the Incorporated Enactments, Full Explanatory Notes Tables, and Examples By ORME CLARKE of the Inner Temple and Western Circuit Barrister at Law With an Introduction by Sir JOHN SIMON, K C V O M P , Solicitor-General Second edition London Winnipeg, Sydney, and Calcutta Butterworth and Co 1913 Pp 636 Price 12*s* 6*d*

WHEN reviewing the first edition of Mr Orme Clarke s excellent text book it was pointed out that the issue of Regulations would probably render a second edition necessary before amendment of the Act took place, or, what would have amounted to the same thing, before its provisions were tested in the working The inclusion of nearly 150 fresh pages in Mr Clarke s second edition is due principally to the publication of the Regulations and these naturally comprise matter with which all those directly or indirectly concerned in working the Act have to render themselves familiar, or at any rate require within their reach for reference The author has not apparently found much to correct in or add to his notes on the text of the Act , but under Section 16 a note on the interpretation of the word "treatment' has been added, and perhaps before Mr Clarke's third edition issues from the press there will be judicial authority upon this subject In discussing Subsection 2 (B) of the same section a very interesting point is raised as to the limitation of the "research' to which the Insurance Commissioners are authorised to devote moneys provided by Parliament Is it to be research in connexion with tuberculosis only? Mr Clarke is inclined to take the wider construction as right and he submits that the Commissioners may devote money to research in relation to any disease which affects insured persons, and consequently the insurance funds It need hardly be said that the adoption of such a view and the vigorous prosecution of research with the object of preventing disease should be more genuinely economical and should do more to render the National Insurance Act of national benefit than any completeness of organisation or administration for curative purposes only

---

Maladies du Pancréas de la Rate et du Mésentère Par G CHAVANNAZ et J GUYOT Professeurs à la Faculté de Médecine Chirurgiens des Hôpitaux de Bordeaux Paris J B Baillière et Fils With 126 figures 1913 Pp 403 Price paper, 10 francs , bound 11 50 francs

THIS is an important section of the Nouveau Traité de Chirurgie of Dentu and Delbet, and it deals with three subjects which often do not receive their full share of notice in treatises on surgery The pancreas has come into the area of surgery only within very recent years , and even at the present time it cannot be said that the surgical treatment of its diseases has reached a perfectly satisfactory level The account given here is excellent, and it not only describes well the present state of our knowledge, but also offers indications of the direction which the surgery of this organ may take.

The clinical examination of the pancreas is fully discussed, and all the tests that have been recommended for the recognition of disease of the pancreas are described. With regard to the Cammidge reaction, the authors limit themselves to saying that though the test deserves to be applied, too much importance must not be placed on the result. The most important chapter is naturally that dealing with the surgery of cysts of the pancreas, for that is the morbid condition for which surgery has the most to offer.

The section dealing with the surgery of the spleen is perhaps even more interesting than that treating of the pancreas. The operation of splenectomy is now performed for a variety of conditions. The authors advise it strongly in Banti's disease; and the statistics in cases not very far advanced and not complicated give a mortality of 18 per cent., which is not very high when the severity of the disease is considered. It is clear that if the best results are to be obtained in this affection the operation must not be postponed to a late stage. In the surgery of the mesentery the part first treated is the effect of the obliteration of the mesenteric vessels, and the tumours of the mesentery are described. The former is a somewhat rare condition about which a good deal has been written in special articles, but which has received but scanty treatment in ordinary surgical works.

Each section of the book has been provided abundantly with bibliographical references. We have found this work on some of the bypaths of surgery very interesting, while its suggestiveness will also make it valuable.

Systematic Case-Taking: a Practical Guide to the Examination and Recording of Medical Cases. For the Use of Medical Students. By Henry Lawrence McKisack, M.D. R.U.I., M.R.C.P. Lond., Physician to the Royal Victoria Hospital, Belfast. London: Baillière, Tindall, and Cox. 1912. Pp. 166. Price 3*s.* 6*d.* net.

Case-taking in the wards is one of the most important and valuable parts of the student's course of clinical instruction, if adequately carried out under systematic methods. Dr. McKisack, in his preface, after pointing out the necessity for personal instruction in the wards in this subject, expresses the view that a methodical syllabus can serve to add completeness and coördination to the student's method of examination. This object his small guide is well calculated to secure, since it is more than a mere catalogue or summary of the procedure concerned in case-taking. Each sign and symptom is briefly but clearly described, together with a short statement of its significance, and in many cases an explanation of its production. The first chapter is devoted to preliminary inquiries, and gives suggestions as to the eliciting of the history, including family history and the history of the patient's symptoms. The general examination is next discussed, and then the various systems and organs are separately considered. In every case the information given is clearly expressed, is well systematised, and is divested of unnecessary technicalities.

Dr. McKisack's book should be a useful companion to the student who is "clerking" in the medical wards, since it affords him a system on which to proceed, and at the same time gives explanations of the conditions observed.

Gynäkologisches Vademekum für Studierende und Aerzte. Von Dr. A. Dührssen, Berlin. With 138 illustrations in the text and 11 plates. Berlin: S. Karger. 1913. Pp. 306. Price 6.80 marks.

There is little need for our commendation of a book which has reached its tenth edition and has been translated into English, French, Italian, Russian, Polish, Turkish, and Greek. The book was originally translated into English by the late Mr. J. W. Taylor and Mr. Frederick Edge, and in this form has no doubt been read by many English students. As Mr. Taylor and Mr. Edge pointed out in the preface to their translation, the work is a clear and safe guide to the knowledge of all the purely gynæcological diseases, and deals very fully with details of the examination of patients, the preparations for operations, and the operations in more general use.

The predilection of the author for the vaginal route in operating is well known, and to him more than to any other gynæcologist are our thanks due for the pioneer work done in this direction. It is not surprising, therefore, that a considerable amount of space is devoted to the various operations which can be performed by this route, and for the surgeon who wishes to obtain a first-hand knowledge of these procedures this little work will prove highly serviceable. Professor Dührssen still holds that a vaginal extirpation of the uterus in cases of carcinoma of the cervix, provided that Schuchardt's incision is employed, gives as good results with a lower death-rate as the extended abdominal operation, and his views on this and on other debatable points in gynæcological practice are naturally of the highest value. A most interesting chapter to the surgeon is the short one dealing with his legal responsibility to his patient. The author describes and recommends Lennander's method of opening the abdominal wall, in which the incision is made to one side of the middle line, the rectus muscle displaced, and then the peritoneum opened medianly; on the closure of the wound the rectus muscle is attached by sutures to its aponeurosis in the mid-line.

There are many other points of interest in this little work which will repay perusal as an expression of the views of one of the most distinguished and original of German gynæcologists.

Die Gallensteinkrankheit und ihre Behandlung vom Standpunkt des inneren Mediziners und Chirurgen. Von Dr. Karl Grube, Professor in Bonn, Arzt für innere Krankheiten in Bad Neuenahr; und Dr. Henry Graff, Professor und Dirigierender Arzt der chirurgischen Abteilung des Marienkrankenhauses auf dem Venusberg in Bonn. Mit 3 Lithogr. tafeln und 20 Textfiguren. Jena: Gustav Fischer. 1912. Pp. 172. Price 7 marks.

This is a very practical treatise on gall-stones, the symptoms to which they give rise, and the treatment which should be employed. After an account of the anatomy of the gall-bladder and the ducts, the various forms of gall-stones are described and the pathological anatomy is discussed. The important subjects of etiology and symptomatology are taken next. The diagnosis and treatment are fully considered. In the latter first comes the preventive treatment of gall-stones; then follows that of acute attacks; the special drugs which are supposed to dissolve gall-stones are mentioned; and of all of them, even of Chologen, from which much has been expected, the authors are able to report nothing of real value. With regard to operative treatment, they consider as suitable for operation: all chronic cases, if the presence of pain interferes with work; all acute cases with acute inflammatory processes and threatening peritonitis or perforation; all chronic inflammatory processes with septic manifestations; all cases with chronic blocking of the common duct; and all cases in which there is a suspicion of malignant disease. The operation should remove every trace of gall-stones, it should clear the biliary passages, and should, so far as possible, prevent the formation of fresh stones. The technique of the operation is well described; most of the incisions which have been recommended for exposing the gall-bladder and bile-ducts are given. The one which the authors prefer is this: They make a longitudinal incision in the outer third of the right rectus, the fibres of which are separated by a blunt instrument, and three fingers' breadth above the umbilicus the incision curves outwards when it can be carried as far as the conditions render necessary The carrying out of the several surgical procedures needed by the conditions found is described Three coloured plates of gall stones and of a dilated gall bladder are given

Geometrical Optics By ARCHIBALD STANLEY PERCIVAL, M A, M B, B C Cantab, Senior Surgeon Northumberland and Durham Eye Infirmary London Longmans, Green and Co 1913 Pp 132 Price 4*s* 6*d* net

Dr Percival is indefatigable in his endeavours to interest and instruct the medical student in the mysteries of ophthalmic optics As all know, he is a safe guide The present book is an expansion and simplification of the more elementary chapters of his larger work on optics He adopts the analytical method, and the array of algebraic symbols and formulæ will be liable to depress the average student, but we hope they will not cause him to abandon the book in discouragement Optics requires thought and not mere absorption of knowledge and thought requires the expenditure of energy which in this case is repaid with compound interest A formula mastered is a mine of knowledge attained, and those who have passed through the mathematical mill will have gained a conception of the optical problems of ophthalmology which will serve them in good stead in the practical details of ophthalmoscopic work and the correction of refractive errors The intelligent student will have no difficulty in following Dr Percival in his exposition of reflection and refraction of light by plane and spherical surfaces The theory of cardinal points is illustrated by the thick lens and the optical system of the eye The paragraphs on graphic methods require more explanation and are particularly worthy of further elucidation In the appendix the elements of reflection and refraction of oblique pencils are discussed, as well as the circle of least diffusion and deviation by prisms The work is well printed and can be cordially recommended

---

LIBRARY TABLE

Annals of Tropical Medicine and Parasitology Series T M, Vol VI, No 4—This number of the Annals contains nine articles upon varied topics some of them being of particular interest The first two are contributed by Dr B Blacklock, and give an account of some experiments on the resistance of the bed bug to various reagents, powders, liquids and gases and another series on the resistance of the tick *ornithodorus moubata* to various sheep dips Dr Blacklock finds no evidence that bed bugs can be cleared out of a house by insecticide powders the same remark applying to liquid remedies, gaseous substances, however offer the best prospect of success sulphur dioxide being cheap as well as effective As regards ticks it appears that when feeding they are not easily caused to loosen their hold by application of sheep dips These dips seem to have very slight effects upon the tick when used in the strength and for the length of time usually recommended —Mr Henry F Carter F E S, furnishes descriptions of three new African species of the genus Tabanus with illustrations —Dr G C Simpson and Mr E S Edie jointly discuss the influence of quinine on hæmoglobin metabolism in malarial fever Increased excretion of urobilin may occur after the administration of quinine in doses of 10 to 30 grains daily A similar result follows injection of blood pigment or hæmolytic drugs Quinine these investigators state possesses the power of determining hæmolysis in the body, though the exact mechanism of its action must be further investigated Individual or pathological idiosyncrasy may exaggerate this action, and so account for the influence of quinine in blackwater fever —An interesting article, illustrated with two plates, on the cultivation of one generation of malarial parasites (plasmodium falciparum) *in vitro*, by Bass's method, is contributed jointly by Dr J G Thomson and Dr S W McLellan, accompanied by a note by Sir Ronald Ross There is indisputable evidence by these investigators of the successful cultivation of plasmodium falciparum up to the sporulating forms —Miss Helen A Adie, of the Malaria Laboratory, Lahore, adverting to a previous communication in THE LANCET of March 30th, 1912 supplies a note (illustrated) on the sex of mosquito larvæ —A joint preliminary communication upon some effects of the occurrence of myxosporidia in the gall bladder of fishes is furnished by Dr H B Fantham and Miss Annie Porter, D Sc, who hope shortly to deal with some of the myxosporidia parasites in greater detail and to discuss more fully the various changes occurring in infected fishes —Dr Allan Kinghorn and Dr Warrington Yorke continue their series of reports upon the work of the Luangwa Sleeping Sickness Commission Upon the present occasion they give further observations on the trypanosomes of game and domestic stock in North Eastern Rhodesia, they also supply, in collaboration with Mr Llewellyn Lloyd, entomologist to the commission an account of their investigations on the development of trypanosoma rhodesiense in glossina morsitans The parasites multiply in a certain proportion of the tsetse flies in the intestine To become infective the salivary glands of the fly must be invaded Dr Kinghorn and Dr Yorke think that probably the salivary glands of the flies become invaded by parasites which have reached a certain stage in their development cycle in the intestine Invasion of the salivary glands was only observed in the case of flies infected with the human trypanosome (T rhodesiense) and not in the case of any of the other trypanosomes with which they had to deal either in the Luangwa valley or on the Congo Zambesi watershed A description of the parasite as it appears in different portions of the tsetse fly is reserved for a further communication

The Students Human Physiology a First Year s Course in the Practice and Theory of the Subject By ERNEST EVANS Natural Science Master Technical Institute, Burnley With 113 illustrations London George Allen and Co Limited 1912 Pp 304 Price 5*s* net —This book it seems has been prepared with the object of showing how a complete course of instruction in the practice and theory of the more elementary parts of human physiology can be given and it is said to contain all the essentials for a first year s course in the subject It is meant for use in schools Much of the teaching is vague and some quite incorrect as it stands however good the author s meaning may be ' The modern science of physiology,' he says, "was established in the sixteenth century by Harvey when he discovered the circulation of the blood Harvey s famous work was published in 1628 The mistake is made throughout of confusing "fixing' of tissues with "hardening ' ' The heart is placed in the middle line of the thorax , "on the upper surface (of the stomach) or lesser curvature the liver rests and on the lower or greater curvature comes the pancreas , ' the blood during its passage through the body is propelled from the ventricles to the auricles by the contraction of the heart , a capillary is a small tubular opening in connective tissue ', the position occupied by the coronary arteries shuts off much of the high pressure which exists in the aorta We have taken these instances at random As to the illustrations, some of them are, to say the least not illustrative such as a transverse section of the neck the fibro cartilage of a cow s ear and fibrin network The diagram of the circulation of the blood (p 104) shows the portal vein springing from what is called systemic

In the year 1911, before notification was universally compulsory, about 35,000 cases of tuberculous phthisis were known to exist in this country, 13,000 of which occurred in Poor-law practice, 12,000 were notified under the new hospital regulations, and 10,000 were reported under local Acts or by voluntary arrangements. Dr. NEWSHOLME expresses the belief that the enforcement of notification of all recognised cases of the disease from the beginning of 1912 will furnish more complete information of its incidence than has previously been obtainable. Although the experience of the first quarter under the new *régime* probably represents a considerable accumulation of cases, it is interesting to learn that within the first three months of 1912 more than 38,000 cases of pulmonary tuberculosis were notified in England and Wales. We now also know from a valuable report of the Public Health Committee of the London County Council that during 1912 there were 33,444 cases of tuberculous phthisis notified in the county, while it is estimated that there are in the area 50,000 persons suffering from tuberculosis. A complete scheme for dealing with this mass of disease has been prepared, and similar steps are being taken all over the country to make diagnosis, prevention, and treatment go together upon a coördinated and economical plan. So that if much remains to be done, at any rate, much is doing.

◆

The History of the Enzyme.

THE belief was expressed more than a decade ago that the group of unorganised ferments which it is now agreed to call enzymes probably played an important rôle in the defence of the human organism against pathogenic micro-organisms, and further, that their action possibly as proteolytic agencies went so far as to destroy toxins. Our knowledge has developed a great deal since, and modern researches have advanced along lines which have strengthened this belief, for at the present time the view rapidly gains ground that the enzyme furnishes a factor of the utmost biological importance to the human organism. For us, the great interest attached to the enzyme is, of course, its function in the human host, but it is curious to reflect that the first really serious study given to these mysterious manipulators of molecular alignment arose not out of pathological curiosity, but from a consideration of certain changes occurring in industrial processes. The story of the enzyme was developed during the study of alcoholic fermentation, and we owe most of our knowledge of the occurrence and mode of action of the enzyme to the brewing industry. To know the pathology of beer was of vital importance to the success of the brewer, and the question was attacked with such perseverance, skill, and activity that it is doubtful whether at the present time any other industry stands on a sounder or less empirical basis than brewing. The pathology of beer was, in fact, studied with such success that the diseases to which it was in the old time heir are now practically eliminated—at all events, in the hands of the progressive technologist. The enzymes concerned were, in the first place, diastase of malt, and, in the second, zymase of yeast. It was the study of the latter enzyme which demonstrated how misleading was the distinction between organised and unorganised ferments. The vitalistic theory of ferments was badly shaken when it was shown that it was not the cell but the secreted substance of the cell which effected the changes summed up in the term "fermentation." The inference of this was that the work of the enzyme is chemical and not physical, and attention forthwith was given to the part played by the enzyme in intracellular metabolism.

At one time the list of ferments was a comparatively small one. The enzyme diastase (or amylase, according to modern nomenclature), which was found to be responsible for changing starch into sugar, as in the brewing process, is probably our oldest acquaintance. It was first observed in 1814, and in 1831 it was discovered that saliva possessed a similar property which we know now to be due to the enzyme ptyalin. A similarly acting enzyme was found in the pancreas in 1845 and in the intestinal juice in 1895, so that the existence of animal diastases was established. The more complicated lysis of proteins, as performed by pepsin and pancreatin or trypsin, does not appear to have received serious attention until 1860. Enzymes were afterwards isolated from plants which showed a similar hydrolytic action, and then the hydrolysing action of acids simulating enzymes upon both carbohydrates and proteins came prominently into notice. In the present day we seem to be going a step farther, for it appears that the work of hydrolysis can be done by metallic ferments, colloids, or by radiations, in the form of ultra-violet rays, or radium emanation, all of which has vast suggestion in the treatment of disease by certain modern methods. It is probable that the list of enzymes with which we are now familiar is only a small representation of the number of these activities which actually exist both in the animal and plant kingdoms, but at the present time we may say broadly that some fifty distinct varieties have been recognised of which the individuality and mode of action have been made clear. Since little is known concerning the nature of the enzymes, their classification so far is based on the chemical reactions which they bring about. The modern nomenclature of the enzymes is of interest. It is generally agreed now to give them the termination "ase," as, for example, lactase, the enzyme which converts lactose into galactose; lipase, the enzyme which converts fat into fatty acids and alcohol. The substance acted upon, which gives the root name to the enzyme, is called the substrate. The terminology adopted has exceptions in the classic examples of pepsin and trypsin.

It is extraordinary what a variety of actions the enzymes are capable of performing. Thus, in addition to those already mentioned, there are enzymes which convert urea into carbon-dioxide and ammonia (urease); further, there are those which oxidise purins, alcohol, aldehyde, phenol, tyrosin (the oxidases); another group sets free oxygen from hydrogen peroxide (the peroxidases and catalases, the action of which is analogous to that of the colloidal metals); again, there are enzymes which convert cellulose into sugar, as in the digestive process of graminivorous feeders (cellulase), and enzymes like chymosin which effects the clotting of milk, and thrombin, which coagulates fibrinogen into fibrin in the blood Then there are the synthetic enzymes, which build up just those molecules which, *it would seem, they are unable to break down,* while some enzymes are able, like the toxins, to cause the production in the living organism of antibodies which retard the action of the enzymes Anti enzymes appear to behave like enzymes in the role of organic catalysts, and the relations between enzymes and anti enzymes are identical with those between toxins and antitoxins The specifically acting secretions produced in the organism in the presence of enzymes by immunisation belong to the group of anti enzymes On the other hand, and lastly, there are the co enzymes or activators, without whose coöperation the enzymic processes do not take place, and which, in fact, accelerate a reaction A good example of activators is enterokinase, the constituent of the intestinal liquid which activates tryptase or trypsin, as was demonstrated in the researches of PAWLOW, BAYLISS, and others Yet another fruitful study is that which is disclosing a group of substances which protect the enzymes on the one hand and those which, on the other, act as "paralysors," inhibiting agents, or poisons

Step by step, thus has the edifice of enzymology grown to its present developments, and how important the results of its study have become must be admitted in view of the relationship which recent researches have shown to exist between the action of the enzymes and the pathogenicity of the disease producing organism It is clear, at all events, that certain enzymes in the human host exercise a profound influence upon the metabolic processes, and it is well, therefore, to refresh our memories with the links in the chain of events, the connecting of which has led to the recognition of a great biochemical system which must in future be reckoned with in any scheme of progressive medicine

Heart Disease in Children.

THE discussion which recently took place at the Royal Society of Medicine in the Section for the Study of Disease in Children on the subject of Heart Disease in Children a full report of which appeared in THE LANCET of Jan 4th, and also in the January number of the Proceedings of the Society, contains matter which deserves the attention of all practitioners of medicine, general and consulting It is interesting both for the evidence it affords as to the consensus of opinion which exists on certain aspects of the question which are hardly enunciated with sufficient emphasis in medical text-books, and for the arguments for and against some more novel views which have not yet obtained universal recognition Among the accepted opinions we may note the view that rheumatic fever in children affects not only the endocardium, on which lesion most emphasis is usually laid but also the muscular substance of the heart, and further, that it is almost as essentially a disease of the heart as it is of the joints Consequently it is to be assumed that there is some affection of the cardiac muscle in all cases, even when none of the accepted signs of such involvement are to be discovered The influence of this view on the treatment of the disease is noteworthy, as it involves the enforcement of a prolonged period of complete rest even after the fever and symptoms of the malady have subsided It can hardly be doubted that such care is urgently called for in all cases of acute rheumatic disease in children, and that many of the cases of chronic incurable valvular defects which are at present so common, especially in hospital practice might have been avoided if the original illness had been more efficiently treated Unfortunately not only has the need of prolonged rest been unrecognised in the past, but the insidious nature of rheumatic infection in the young has been disregarded, and such symptoms as fever, anæmia, and slight pains in the limbs have been neglected both by parents and doctors, the child being said to suffer from the mythical condition of “growing pains” or the favourite domestic ailments, bilious attacks and sore throats

As to the treatment of acute rheumatism when recognised, useful advice is to be found in this discussion, the invaluable rest in bed being assisted by low diet of a vegetable nature by adequate purgation, by diuretics, and by salicylate of sodium Whether this last remedy has any *efficacy against cardiac involvement is a question upon* which different speakers held divergent views and it is probably wise to avoid heroic doses of a depressant drug if the heart's action is unsatisfactory Nevertheless, in view of the remarkable effects of this drug in reducing fever and articular troubles it is natural to credit it with some efficacy against the same toxin in other tissues, *and it seems advisable to give it a trial in cases of acute* cardiac involvement which are definitely rheumatic in origin A similar doubt prevails as to the utility of digitalis in cases of myocardial disease, the older view being that in such conditions the muscle cannot respond to the stimulant while more recent practice seems to favour a trial of some preparation of digitalis even when there is proof of myocardial affection It should hardly be necessary to point out the uselessness or worse of ordering digitalis as a routine treatment in all cases in which a cardiac murmur is heard, however good the compensation that exists, but experience shows that there is still a tendency to regard the drug as a panacea for all valvular lesions, whatever their nature and whatever the general condition of the circulation, so that a repetition of the warning may not be useless The value of local applications to the chest wall is another subject on which opinion is divided In cases of pericarditis the balance of opinion is probably in their favour On the other hand, it is difficult to believe that the application of an ice-bag or a blister can affect a condition of inflammation of the endocardium Nevertheless, these remedies have their defenders A point on which opinion was even more divided, and as to which the truth can hardly be said to be established, was the question as to the existence of functional disorder of the heart in children This was stoutly affirmed and denied, some speakers regarding almost all irregularities of rhythm as indications of myocardial disease, others holding that they were frequently of little importance Probably the truth lies as usual between the extreme views It is necessary to distinguish the different groups of cases in which irregularities of rhythm occur, those which are purely

In the year 1911, before notification was universally compulsory, about 35,000 cases of tuberculous phthisis were known to exist in this country, 13,000 of which occurred in Poor-law practice, 12,000 were notified under the new hospital regulations, and 10,000 were reported under local Acts or by voluntary arrangements. Dr. NEWSHOLME expresses the belief that the enforcement of notification of all recognised cases of the disease from the beginning of 1912 will furnish more complete information of its incidence than has previously been obtainable. Although the experience of the first quarter under the new *régime* probably represents a considerable accumulation of cases, it is interesting to learn that within the first three months of 1912 more than 38,000 cases of pulmonary tuberculosis were notified in England and Wales. We now also know from a valuable report of the Public Health Committee of the London County Council that during 1912 there were 33,444 cases of tuberculous phthisis notified in the county, while it is estimated that there are in the area 50,000 persons suffering from tuberculosis. A complete scheme for dealing with this mass of disease has been prepared, and similar steps are being taken all over the country to make diagnosis, prevention, and treatment go together upon a coördinated and economical plan. So that if much remains to be done, at any rate, much is doing.

The History of the Enzyme.

THE belief was expressed more than a decade ago that the group of unorganised ferments which it is now agreed to call enzymes probably played an important rôle in the defence of the human organism against pathogenic micro-organisms, and further, that their action possibly as proteolytic agencies went so far as to destroy toxins. Our knowledge has developed a great deal since, and modern researches have advanced along lines which have strengthened this belief, for at the present time the view rapidly gains ground that the enzyme furnishes a factor of the utmost biological importance to the human organism. For us, the great interest attached to the enzyme is, of course, its function in the human host, but it is curious to reflect that the first really serious study given to these mysterious manipulators of molecular alignment arose not out of pathological curiosity, but from a consideration of certain changes occurring in industrial processes. The story of the enzyme was developed during the study of alcoholic fermentation, and we owe most of our knowledge of the occurrence and mode of action of the enzyme to the brewing industry. To know the pathology of beer was of vital importance to the success of the brewer, and the question was attacked with such perseverance, skill, and activity that it is doubtful whether at the present time any other industry stands on a sounder or less empirical basis than brewing. The pathology of beer was, in fact, studied with such success that the diseases to which it was in the old time heir are now practically eliminated—at all events, in the hands of the progressive technologist. The enzymes concerned were, in the first place, diastase of malt, and, in the second, zymase of yeast. It was the study of the latter enzyme which demonstrated how misleading was the distinction between organised and unorganised ferments. The vitalistic theory of ferments was badly shaken when it was shown that it was not the cell but the secreted substance of the cell which effected the changes summed up in the term "fermentation." The inference of this was that the work of the enzyme is chemical and not physical, and attention forthwith was given to the part played by the enzyme in intracellular metabolism.

At one time the list of ferments was a comparatively small one. The enzyme diastase (or amylase, according to modern nomenclature), which was found to be responsible for changing starch into sugar, as in the brewing process, is probably our oldest acquaintance. It was first observed in 1814, and in 1831 it was discovered that saliva possessed a similar property which we know now to be due to the enzyme ptyalin. A similarly acting enzyme was found in the pancreas in 1845 and in the intestinal juice in 1895, so that the existence of animal diastases was established. The more complicated lysis of proteins, as performed by pepsin and pancreatin or trypsin, does not appear to have received serious attention until 1860. Enzymes were afterwards isolated from plants which showed a similar hydrolytic action, and then the hydrolysing action of acids simulating enzymes upon both carbohydrates and proteins came prominently into notice. In the present day we seem to be going a step farther, for it appears that the work of hydrolysis can be done by metallic ferments, colloids, or by radiations, in the form of ultra-violet rays, or radium emanation, all of which has vast suggestion in the treatment of disease by certain modern methods. It is probable that the list of enzymes with which we are now familiar is only a small representation of the number of these activities which actually exist both in the animal and plant kingdoms, but at the present time we may say broadly that some fifty distinct varieties have been recognised of which the individuality and mode of action have been made clear. Since little is known concerning the nature of the enzymes, their classification so far is based on the chemical reactions which they bring about. The modern nomenclature of the enzymes is of interest. It is generally agreed now to give them the termination "ase," as, for example, lactase, the enzyme which converts lactose into galactose; lipase, the enzyme which converts fat into fatty acids and alcohol. The substance acted upon, which gives the root name to the enzyme, is called the substrate. The terminology adopted has exceptions in the classic examples of pepsin and trypsin.

It is extraordinary what a variety of actions the enzymes are capable of performing. Thus, in addition to those already mentioned, there are enzymes which convert urea into carbon-dioxide and ammonia (urease); further, there are those which oxidise purins, alcohol, aldehyde, phenol, tyrosin (the oxidases); another group sets free oxygen from hydrogen peroxide (the peroxidases and catalases, the action of which is analogous to that of the colloidal metals); again, there are enzymes which convert cellulose into sugar, as in the digestive process of graminivorous feeders (cellulase), and enzymes like chymosin, merely occluded materials expelled from the bulb, or whether they are transmutations of hydrogen or aluminium

SOFTENING OF THE SPINAL CORD IN A SYPHILITIC AFTER AN INJECTION OF SALVARSAN

A young man aged 23 received from June 1st to Sept 3rd, 1908 a series of intramuscular injections of corrosive sublimate for a syphilitic roseola which had followed on a typical indurated sore On March 24th 1910 he returned because of a cutaneous syphilide and extensive adenitis and was treated with similar injections for six days Then instead of them he was given two injections of salicylate of mercury a week intervening between these He was seen again on May 30th, 1911, adenitis being still noted and on June 10th at noon 0 3 gramme salvarsan was injected into each buttock At the time there were no manifestations of syphilis whatever except the condition of the glands On the evening of June 12th having been perfectly well in the intervening 56 hours, the patient felt a numbness in his legs and fatigue in them, and soon after had difficulty in passing urine During the next day the condition rapidly advanced and on June 14th there was a complete motor and sensory paraplegia With bladder and rectum paralysed and bed sores and other trophic disorders setting in his condition was serious from the beginning and in spite of every effort he died on August 29th Subsequent pathological examination showed an acute syphilitic softening at the level of the fourth and fifth thoracic segments the morbid change being more advanced in the postero lateral columns than in the anterior Meningeal and vascular lesions were marked throughout Such is the history as given by Dr Leo Newmark of San Francisco (who was called in consultation) in the *American Journal of the Medical Sciences* for December last and the question naturally suggests itself If a young man who has been infected with syphilis three years previously presents the first symptoms of a fatal softening of the cord 56 hours after an injection of salvarsan is the drug in any way to blame for the condition which followed its injection? There is no doubt, of course that clinically and anatomically the evidence in favour of the sufficiency of syphilis to produce the disease of the cord is complete and there would appear to be no room for the intervention of salvarsan Moreover, if the close sequence of drug and disaster as Dr Newmark says impresses us with a sense of cause and effect it must not be forgotten that occasionally serious damage to the central nervous system has followed an injection of mercury But long use of mercury has shown such incidents to be so rare as to be negligible whereas there is to-day a growing list of affections of the cranial nerves brain or cord subsequent to the administration of salvarsan Dr Newmark is inclined to admit that the salvarsan in his case was somehow an agent in the final result and adduces the Herxheimer reaction as a possible explanation

THE ALL-INDIA SANITARY CONFERENCE

At this important gathering held in Madras from Nov 11th to the 14th last—a brief report of which we begin this week from our Indian correspondents—the subjects for discussion were considered in two sections a medical and an engineering section, which also met jointly Sir Harcourt Butler the Member for Education on the Governor General's Council presided and there was a full attendance of delegates from all parts of India and Burma In his opening address the President alluded to the recent reorganisation of the offices of the Director General, Indian Medical Service and of the Sanitary Commissioner with the Government of India and to the development of the sanitary service generally Large grants will be made for antimalarial measures during the past year more than two lakhs of rupees have already been allotted in the United Provinces, Bombay Bengal and Madras in aid of investigations into the conditions causing malaria, and of antimalarial schemes, in future such financial assistance will only be given for actual works of amelioration or removal of malarial conditions An interesting paper was read by Mr E G Turner on Town Planning in Bombay the lines on which this is being carried on are a combination of the German principle of "redistribution (which gives power to alter the shape of holdings of land so as to render them more suitable for building plots) with the English principle of "betterment (which enforces contributions from owners towards the cost of a scheme in proportion to the extent to which their land is bettered by the completed scheme) Mr J P Orr chairman of the City of Bombay Improvement Trust read a very practical paper on Light and Air in Bombay In that city of 980 000 inhabitants 85 per cent of the population live in single tenements The Improvement Trust had only touched 10 per cent of the congested areas The difficulties are enormous but under Mr Orr's guidance great amelioration is rapidly being effected He laid down that partial improvement was no good A standard must be fixed and rigidly adhered to obstructive dwellings must be removed new building operations controlled and great improvement made in the admission of light and air Among other subjects dealt with were the scope of preventive measures against plague the recent diminution in enteric fever prevalence the treatment of urban water supplies and sewage and refuse disposal according to recent methods as at present carried out in India

CIRCUMSCRIBED PERITONITIS DUE TO INTESTINAL PERFORATION IN TYPHOID FEVER

That perforation of a gastric ulcer sometimes produces only local peritonitis and adhesions is recognised but a similar condition as the result of perforation of the intestine in typhoid fever is not well known At a meeting of the Société Médicale des Hôpitaux of Paris on Dec 13th last M Ch Achard and M G Desbouis reported the following case A man aged 31 years was admitted into the Necker Hospital on Sept 16th 1912 complaining of diarrhœa and abdominal pains from which he had suffered for a fortnight His illness began on Sept 2nd with pains in the right iliac fossa, rigors fever and vomiting For some months previously he had lost flesh and suffered from a persistent cough and night sweats At the time of admission his wife and two children were under treatment for typhoid fever On admission he was in a prostrate and somnolent state The tongue was normal and the breath was fœtid The abdomen was a little tense but showed no tender spot gurgling in the iliac fossa or rose spots The spleen was enlarged At the apex of the right lung there were signs of a softening tuberculous lesion The pulse was 98 strong and hard The temperature was 101 5° F On the 17th four or five rose spots appeared on the flanks and on the 18th there was an abundant eruption and the abdomen was distended The serum reaction was positive The patient remained in a state of complete adynamia and the temperature fell to 100°, while the pulse rose to 120 On the 23rd he was seized with violent pain at first above and to the left of the umbilicus then rapidly spreading to the whole abdomen Nausea and porraceous vomiting followed The abdomen became hard very tense and very tympanitic and the hepatic dulness completely disappeared The diarrhœa ceased the temperature fell to 98 2° and the pulse was 150 and filiform On the 25th there was absolute constipation and micturition was impossible Very fœtid vomiting occurred four or five times, and on the last occasion it was almost fæcal. There was also hiccough. The patient's condition was considered too grave for operation; opium was given and ice applied to the abdomen. He remained in this state on the 26th and 27th, the vomiting being a little less frequent. Liquid was found in the flanks. On the 28th the vomiting had ceased, the abdomen was more supple, and dulness could no longer be found in the flanks. Urine had been passed. On the 29th the constipation had ceased and the mental condition was improved, he could answer questions better, and the abdomen was perfectly supple. On the 30th the general condition was satisfactory, the temperature was 99·3°, and the pulse was 96 and good. The stools were formed. On Oct. 1st the patient complained of pain in the ear, and the left parotid gland was found swollen and tender. The temperature had risen to 100·4°. On the 2nd the right parotid was similarly affected and torpor had recommenced. The temperature was 100·4° and the pulse 140. On the 3rd the patient died comatose. The necropsy showed tuberculous infiltration of both apices and a cavity of the size of a walnut at the right. The coils of the ileum were agglutinated into a mass in the right iliac fossa. This mass was partitioned by adhesions. On carefully breaking these, eight perforations were found within a distance of 12 centimetres from the ileo-cæcal valve. They varied in size from the head of a pin to a 50-centime piece, and were closed either by mesentery or adhesions to neighbouring coils. The spleen was very large and diffluent. In this case all the symptoms of perforation occurred with characteristic suddenness—violent abdominal pain on the left side, vomiting, hiccough, abdominal rigidity, meteorism obliterating the hepatic dulness and followed by dulness in the flanks, retention of urine, arrest of diarrhœa, sudden fall of temperature, and frequency and smallness of pulse. These symptoms disappeared, formed stools were passed, the temperature and pulse became normal, urine was passed in abundance, and the abdomen regained its suppleness. All seemed going on well until the attack of double parotitis. The necropsy revealed only circumscribed peritonitis and eight perforations undergoing cicatrisation. This case shows that grave symptoms of perforation may disappear rapidly, and that even multiple perforations may produce only localised peritonitis tending to recovery. Spontaneous recovery from certain intestinal perforations has been known for a long time. Chantemesse insisted in 1908 that this could be produced by adhesion to the omentum.

ATMOSPHERIC POLLUTION.

AT the conference of delegates of local authorities and learned societies convened by the Coal Smoke Abatement Society in connexion with the International Smoke Abatement Exhibition in March last, attention was drawn to the desirability of steps being taken to decide upon and secure the general adoption of a standard method for the measurement of atmospheric pollution by smoke and other products of combustion and dust. A committee was appointed "to draw up details of a standard soot and dust measurement apparatus and methods of its use." The committee is presided over by Dr. W. H. Shaw (Director, Meteorological Office), and its other members include Dr. John Owens, Dr. H. A. Des Vœux, Dr. R. Lessing, and Mr. F. G. Clark (representing the Coal Smoke Abatement Society), Professor J. B. Cohen (Leeds University), Bailie W. Smith (convener of the Air Purification Committee of the Glasgow Corporation), Dr. Hawksley (assistant medical officer of health, Liverpool), Mr. J. B. C. Kershaw (Hamburg Smoke Abatement Society), Mr. S. A. Vasey (THE LANCET), and Mr. E. D. Simon (Smoke Abatement League). The method of investigation, which, after full inquiry, has now been adopted by the committee as most likely to give satisfactory results is that used in the inquiry, conducted in 1911-12 under the auspices of THE LANCET, with the object of ascertaining the degree of pollution of the atmosphere in and around the metropolis. The standard apparatus recommended takes the form of an enlarged rain gauge, having a catchment area of 4 square feet, which receives all rain, soot, and other matters falling thereon, and deposits them in a large bottle, the contents of which can be regularly analysed. The committee's report and recommendation have recently been submitted to all important cities in the United Kingdom, with the result that Birmingham, Bradford, Glasgow, Leicester, Malvern, and Newcastle-on-Tyne have already agreed to set up the standard apparatus in accordance with the committee's advice, and a large number of other towns are favourably considering the proposal. The importance of obtaining on a standardised system reliable information as to the state of the atmosphere in different parts of the country can scarcely be over-estimated. The results will, it is hoped, throw light upon the purity or pollution of the air in different localities. They are also expected to give explanations of the prevalence of chest diseases in certain districts, and will record in a uniform and scientific manner the effect of efforts to purify the air from smoke, sulphurous gases, dust, and other noxious matters. Dr. John Owens, 47, Victoria-street, Westminster, is acting as honorary secretary to the committee.

PASSIVE HUMAN CARRIAGE OF THE VIRUS OF POLIOMYELITIS.

IN the *Journal of the American Medical Association* for Jan. 18th is a brief note by Dr. Simon Flexner, Dr. Paul F. Clark, and Dr. Francis R. Fraser, of the Rockefeller Institute, concerning the question of poliomyelitis carriers. A little girl, aged 4 years and 4 months, was admitted to the hospital of the Rockefeller Institute on Oct. 18th, 1912, less than one week from the development of an attack of poliomyelitis involving mainly the lower extremities. On Oct. 28th the mother and father of the patient were subjected to a naso-pharyngeal irrigation with normal saline solution. Some 150 c.c. of fluid were collected, shaken, and pressed through a Berkefeld filter. The fluid was forthwith injected into a macaque monkey, 1·5 c.c. into each sciatic nerve and 140 c.c. into the peritoneal cavity. On Nov. 11th the animal was noted to be excitable and to drag the right leg, and the next day both legs were definitely paresed. A leucocytosis was found in its cerebro-spinal fluid. On the 13th it was killed under an anæsthetic, when the spinal cord was seen to be œdematous, and sections subsequently were found to present the typical lesions of experimental poliomyelitis. On Dec. 3rd an emulsion of the glycerinated spinal cord of this monkey was injected into each sciatic nerve and into the peritoneal cavity of two other macaques, which in their turn, after an interval of 10 and 16 days respectively, were found to be paresed or paralysed in the legs, and in each instance the typical infiltrative lesions of poliomyelitis were found in the spinal cord. From these experiments it may be fairly concluded that the washings from the naso-pharynx of the parents, neither of whom showed any symptoms of illness and were not suffering from the disease, contained the virus of epidemic poliomyelitis. Thus an experimental basis has been established for the belief, based on clinical observation, of the occurrence of passive human carriers of the infection. The obstacles in the way of demonstrating this important phenomenon experimentally have been considerable. At present the sole means of detecting the virus is by its implantation in monkeys, and it is known that the initial infectivity for monkeys of human strains of the virus varies greatly Large quantities of an emulsion may be required for inoculation It is to be presumed, further, that passive carriers will harbour the virus in smaller amount than persons actively ill with the disease And, again, saline washings of the naso pharynx must dilute the virus materially In view of these facts, experimental failure is more likely to occur than is success, but at the same time they give to a successful result an intensified value

THE AFRICAN BLACKWATER FEVER INQUIRY

IN THE LANCET of Jan 25th we made some observations upon a series of reports on blackwater fever forwarded from some of our tropical African colonies to the Colonial Office, being contributions to an inquiry which has been instituted by the Secretary of State into the nature and causation of that disease Since then another report[1] has been published separately dealing with the disease in Southern Nigeria and prepared by Dr W M Graham director of the Medical *Research Institute at Lagos In this report the scope of* reference indicated by the Colonial Office has not been strictly adhered to, instead, in view of the importance of the subject and the unfixed state of medical opinion about the disease, Dr Graham has supplied what amounts to a short treatise upon the present day knowledge of the malady His aim has been rather to suggest methods of inquiry than attempt to prove the correctness of any one of the various theories which have been put forward *concerning the nature* of blackwater fever The field for observation in the West African colonies is known to be wide in extent as well as rich in material and it is suggested that if medical records were accurately kept upon a uniform plan the next 10 years would see the removal of some, if not all, of the obscurity that now envelops the causation of the malady The different views at present held as to the origin of blackwater fever are passed in review by Dr Graham, and the arguments for and against each are fully discussed In connexion with the opinion which attributes the disease to an infection by a specific organism, the question of direct and indirect transmission is dealt with in an interesting fashion Indirect conveyance of the infection might occur through the common use of domestic utensils, but of more importance we think, is the probable transmission through the agency of parasites, such as fleas, lice bugs, ticks, &c The African servants sleep together or with their relatives in the native quarter of the town or settlement Both native women and children often harbour pediculus vestimenti or pediculus pubis It would be easy for a native servant in the immediate environment of his master, to transfer parasites from his own person to that of his master or to his master s clothing or bedding For successful direct infection, however, personal contact with the native would be necessary, and this in the *majority of instances could* only occur during sexual intercourse In West Africa sexual relations with native women appear to be not very rare, and in non official circles they are commonly acknowledged The native woman often lives in the white man's house, directs his servants, and helps him in his business The opinion seems to be fairly general among non medically educated Europeans in West Africa that blackwater fever is frequently caused by habitual sexual relations with native women, and Dr Graham seems inclined to admit that there may be some kind of ground for this belief He says that if the malady be due to a specific infection, it would almost certainly be present in its most intense form among native women and children in process of acquiring immunity Contact with native children would be the most effective way of contracting the disease For most Europeans, missionaries excepted, opportunities for contact with native children are extremely rare under social conditions, but once a native woman is admitted to intimate relations with a European the opportunities for such contact would naturally increase Dr Graham goes on to say that whatever hypothesis as to the origin of blackwater fever be accepted, malarial or specific, the presence of native women, and their corollary native children, in a European s household in Africa is undesirable, and the danger of their presence is not *diminished when the accompanying children are the natural* offspring of the European himself Dr Graham also discusses the possible relation between the abuse of alcohol in the tropics and blackwater fever The misuse of alcohol is responsible in his opinion for a great deal of ill health on the West Coast of Africa, it binds the oxygen more firmly to the hæmoglobin of the red corpuscles, and thus diminishes their power of oxygenation The result is a *feeling of lassitude and disinclination for mental work* Wright, as quoted by Ehrlich has demonstrated that the ingestion of alcohol is followed by a diminution of the coagulability of the blood Lastly, Dr Graham points out that a drunken man exposes himself needlessly to the attacks of mosquitoes, and that he forgets to take his prophylactic quinine regularly, moreover, he is apt blindly and recklessly to indulge in sexual intercourse with native women

SACRODYNIA IN CANCER OF THE PANCREAS

THE diagnosis of cancer of the pancreas is often missed because symptoms pointing to the disease are wanting Of these the most important is pain extending from the epigastrium to the back The following case, reported at a meeting of the Société Medicale des Hopitaux of Paris on Nov 22nd by MM Marcel Labbe and André Gendron, shows that the pain may be situated so far from its usual site that no suspicion of the disease may be aroused A man, aged 55 years, a masseur, enjoyed good health until Christmas 1911, when on putting coal on the fire he felt a pain at the base of the chest on the left side This pain persisted in spite of the administration of anodyne cachets and the use of liniments He continued to work until April, 1912, but had to lie down several times a day to relieve the pain In February the pain extended to the middle line and then to the right hypochondrium, so that pain of the girdle type was produced The pain was at its maximum on the left side, in the middle line it was acute and on the right side dull From April the patient localised the pain in the sacral region It increased, and rendered walking painful and work impossible It was continuous, with violent exacerbations There were crises, which began by an increase of the sacral pain This reached its maximum in about an hour, and then the patient lost consciousness for several hours An injection of morphine was given, after which he slept for two or three hours The crises were not accompanied by either nausea or vomiting On August 16th he was taken to hospital in a crisis and delirious, in which state he continued until the 20th Examination on that day showed a condition of *mental confusion He attempted to get out of bed trembled* and had carphology He passed urine in the bed There were no signs of organic disease of the nervous system Lumbar puncture was performed and yielded turbid albuminous fluid containing intact polynuclear cells On the 21st he had regained consciousness and clearly gave his history He complained only of pain in the sacral region which, as well as the perineum, was tender, but no objective alteration of sensibility could be found The pain rendered the sitting or lying position difficult. The patient constantly lay with his legs flexed and his body bent, so that his head was between his knees. Every movement increased the pain. Abdominal palpation revealed nothing abnormal. On the 23rd lumbar puncture was performed and yielded a clear non-albuminous fluid. The patient became more and more cachectic. The pain was relieved only by morphine. Neither nausea nor vomiting ever occurred. One or two pasty stools were passed daily. During the first half of September the temperature was 100·4° F., then it fell to 98·6°. The urine did not contain sugar. Death occurred on Oct. 20th. The necropsy revealed a mass of the size of an infant's head in the left hypochondrium, enveloping all the pancreas except the head. The bile-duct was not compressed. The posterior wall of the stomach, terminal portion of the duodenum, transverse colon, and spleen were adherent to the tumour. The aorta and mesenteric vessels were surrounded by the tumour. There were cancerous nodules in the liver. The vertebral column was not invaded. The localisation of the pain in cancer of the pancreas in the sacral region does not appear to have been previously described. In this case cancer was suspected, but, in consequence of the position of the pain, in the pelvis. However, the doubled-up position adopted by the patient to relieve that pain has been several times described in cancer of the pancreas. Possibly the pain was due to compression of sympathetic nerves which finally involved the filaments of the sacral region. But why the pain became confined to this region cannot be explained. A similar localisation is sometimes observed in Pott's disease, in which the pain may be felt lower than the level of the involved roots.

[1] Report on Blackwater Fever in Southern Nigeria 1899-1911 by Dr W M Graham Director of the Medical Research Institute Lagos London Waterlow and Sons 1912 Pp 72 with a number of plates *charts, and maps*

CONTRACTION OF THE DENTAL ARCH AND NASAL STENOSIS.

Dr. Matthew Cryer[1] deals at considerable length with the relation of contracted dental arches to nasal respiration in a contribution to this periodical. In his opinion the effect of the narrow arch is to compress the tongue and force it back into the oro-pharynx. The tongue, he says, "pushes up the soft palate against the post-pharyngeal wall and cuts off respiration through the nose. As the tongue forces the epiglottis downwards and backwards it also interferes with oral respiration, which, however, is a little easier than nasal respiration under these circumstances; hence 'mouth-breathing.'" Spreading the dental arch he considers gives relief to the nasal obstruction by allowing more room for the tongue, which moves forward and releases the pressure on the soft palate and other structures. The view taken by some authors that the beneficial effect on the nasal respiration is due to the opening of the intermaxillary suture and a widening of the floor of the nose is, in his opinion, incompatible with the anatomical structure of the parts involved. He points out that the malar processes, the malar bones, and the zygomatic arches, with their attachments to the sides of the brain case, form the lateral abutments of the maxillæ, and that these abutments are braced by the pterygoid processes and the vertical plates of the palate bones. These are permanent structures of comparatively hard tissues, whereas the bone of the alveolar process is of a far softer character, and it does not seem to him that pressure upon the latter could succeed in opening the maxillary bones which are so firmly held in position. The supporters of the idea that the suture between the intermaxillary bones opens, base their statements mainly on the appearances seen in radiographs. The distortion of radiographs of the upper teeth is well known, and in addition there is the extreme difficulty of taking two pictures at the same angle, so that evidence of this character is liable to be untrustworthy. Dr. Cryer, too, shows by a study of normal skulls that radiograph appearances of the normal suture frequently suggest that an opening exists. There is, in his opinion, no foundation for the idea that a definite relationship exists between the dental or palatal arch and the nasal floor. In support of his opinion he gives illustrations of skulls with narrow palates and wide nasal floors, and others with narrow nasal floors and wide palates. The production of the narrow dental arch so often seen in association with long-continued nasal obstruction, he thinks may in some measure be due to the tension of the palato-glossus and palato-pharyngeus muscles. The contribution is a thoroughly interesting one.

Mr. Edmund Owen's paper on Appendicitis: A Plea for Immediate Operation, which he read before the Medical Society of London on Feb. 10th (*vide* p. 441), was followed by a highly interesting discussion, in which Mr. W. H. Battle, Mr. C. P. Childe, Mr. J. Grey Turner, Mr. A. H. Burgess, Mr. G. R. Turner, Major A. J. Hull, R.A.M.C., Mr. A. M. Connell, Mr. W. H. Clayton-Greene, and Sir W. Watson Cheyne, the President, took part. A full report of the debate will appear in the next issue of THE LANCET.

THE death occurred on Feb. 10th of Mr. Malcolm Macdonald McHardy, formerly professor of ophthalmology at King's College, London, senior ophthalmic surgeon to King's College Hospital, and consulting surgeon to the Royal Eye Hospital.

THE ORGANISATION IN LONDON OF THE TREATMENT OF TUBERCULOSIS.

IN reply to the letter recently received from the Local Government Board suggesting that the London County Council should prepare a complete scheme for dealing with tuberculosis in London,[1] the Public Health Committee reported to the Council on Feb. 11th in favour of accepting the suggestion and outlining the general principles upon which it considered provision for treatment of tuberculosis should be made.

The committee first discussed in detail the clauses of the National Insurance Act bearing on the question, and summarised the recommendations of the Departmental Committee on Tuberculosis appointed in April, 1912, with which the Local Government Board had stated itself to be in general agreement. As to the action taken by the Board, the committee pointed out that, although communications had been addressed to county councils throughout the country as early as May, 1912, no indication was given until December, 1912, as to what authority was to be responsible for dealing with the disease in London. The Council, therefore, was in no way responsible for the delay that had occurred in making arrangements for the treatment of tuberculosis in London. Indeed, as soon as the Council was approached it decided to make temporary arrangements with the Metropolitan Asylums Board for the provision of a limited amount of accommodation. Authority to provide this was received on Dec. 11th, 1912, and although various alterations to buildings had been necessary patients were received on Feb. 10th, 1913.

Incidence of Tuberculosis.

As to the requirements of London and the existing provision for dealing with tuberculosis, the committee said it was difficult to estimate accurately the number of cases within the county, because the disease in all its forms had only just become compulsorily notifiable. There were, however, 33,384 cases of phthisis notified during 1912, of which 12,366 were Poor-law cases, 12,214 were hospital cases, 500 were school cases, and the remainder (8304) were notified by general practitioners. The medical officer estimated that there were in London 50,000 persons suffering from tuberculosis, and of these about 20,000 were insured persons. As regards school children, with the extension of medical re-inspection and the increasing facilities for diagnosis likely to obtain in the near future, it was probable that many more cases of early tuberculosis would be detected each year than had hitherto been the case. The existing provision was in the hands of the various public authorities and of the voluntary agencies comprising the general and special hospitals, the tuberculosis dispensaries, and various philanthropic and religious bodies.

[1] THE LANCET, Dec. 21st, 1912, p. 1743.

Recognition of Existing Agencies for Treatment.

It was obvious that if the best results were to be obtained the work of these authorities and institutions must be coördinated. For instance, under the existing arrangements, the provision of dispensaries was being dealt with by the borough councils. Although it was not suggested that this arrangement was undesirable, it was essential that there should be uniformity in regard to the dispensaries. Moreover, it was very important that the part played by the hospitals, general and special, should not be displaced by any newer dispensary provision. It was equally important that the valuable work of the practitioner should be assimilated in the new arrangements to be made. The dispensaries, if established as separate institutions, should fill up the gaps where the hospital provision was inadequate. It would be a great misfortune if the hospitals, with their highly experienced staffs, elaborate equipment, and special organisation, perfected through a mature experience, were not utilised in any future arrangements. No new institutions with their limited staff and resources could possibly provide the skill and experience available in the large general and special hospitals, and unless these were still to be utilised there would be irreparable loss to the persons suffering from tuberculosis, to whom hitherto these institutions had been available. It had to be borne in mind that in the large hospitals had been evolved to a great extent the forms of medical treatment now accepted as the best, and the progress of medicine was bound up with their keeping in intimate touch with the patients whom hitherto they had extensively treated. To conserve the work of these great institutions rather than replace it should be a definite aim in any reorganisation of the steps for dealing with tuberculosis now undertaken.

If it was considered desirable to coördinate the dispensary arrangements throughout London, uniform agreements should be made between the County Council and the borough councils, and the coöperation of the general practitioner, in cases not suitable for dispensary treatment, should be secured to the fullest extent possible.

One Central Authority for Administration.

The committee proceeded to point out that any measures for the prevention of infection from tuberculosis could not be confined logically to one class. The treatment of the disease could not be regarded as other than a matter of public health administration. This being so, the County Council, in its position of central public health authority, was obviously best fitted to organise the arrangements, as it was important that there should be no departure in London from the well-founded principle of having one central health authority for the administration and coördination of all matters relating to public health. In this connexion the committee indicated the important functions already exercised by the Council in regard to tuberculosis. In its function of education authority, also, it had, to quote the Departmental Committee on Tuberculosis, "the opportunity of playing a very important and indeed essential part in the detection, prevention, and treatment of tuberculosis."

Consultation with Existing Organisations.

For the reasons given the committee was of opinion that the Council should cause a detailed scheme to be prepared for the treatment of tuberculosis. It would be undesirable at this stage to indicate further any details of the scheme, because so many authorities and institutions were concerned that their views must of necessity be ascertained in the first instance. It was important, however, that the action which the Council was to take with regard to the general situation should be decided as soon as possible. The local authorities, hospitals, and all concerned in the provision of treatment for tuberculous persons in London were experiencing considerable difficulty in deciding what arrangements they were to make for the future because of the absence of any coördinating scheme. The question of finance was, of course, of paramount importance as bearing upon the scope of any scheme which might be prepared, and the ideal public health measure must be subordinated to the practical.

Major H. C. LEVITA, chairman of the Public Health Committee, moved the adoption of the following recommendation attached to the report:—

> That it be referred to the Public Health Committee to prepare forthwith and submit to the Council a scheme for dealing with tuberculosis throughout the Administrative County of London, that the Local Government Board be informed of the action taken, and that, for the purpose of preparing a scheme, the committee be authorised to confer with the sanitary authorities, the Insurance Committee for London, and such other authorities, institutions, or persons as the committee may deem necessary.

The Council approved the recommendation of the committee.

MEDICINE AND THE LAW.

Two Cases of Alleged Ptomaine Poisoning.

IN the High Court of Justice recently Mr. Justice Darling with a special jury tried an action brought by a lady named [illegible] ny, [illegible] the [illegible] of the defendants' servants The plaintiff, a trained nurse, occupied rooms in a block of buildings owned by the defendants, in which meals were served to the tenants in a common restaurant, and she gave evidence alleging that she had contracted ptomaine poisoning by eating certain boiled mutton at a dinner in the restaurant on a certain day. Medical and other evidence was called on her behalf, but the lady superintendent of the flats gave evidence, supported by her books, that boiled mutton had not been served in the restaurant on the day on which the plaintiff claimed to have been made ill by it. The plaintiff had also admitted in her evidence that she had contracted dysentery twice in South Africa and since then had suffered from colitis. Dr. O. F. F. Grünbaum gave expert evidence to the effect that acute colitis might be mistaken for ptomaine poisoning, and as to the imprudence of the plaintiff in playing a match at croquet on the day after she was first taken ill, as she had admitted having done. A verdict was found for the defendants.

Two days later, before Mr. Justice Horridge and a special jury, a case was heard in which the plaintiff, Mr. Cheverton, assistant manager to the firm of Pathé Frères, sued M. Pasquier in respect of poisoning which he ascribed to sardines eaten at the Mont Blanc restaurant kept by the defendant in Gerrard-street, Soho. The plaintiff relied upon the implied warranty of the defendant that the food supplied by him was fit for human consumption (Section 14 (1) of the Sale of Goods Act, 1893), and in the alternative alleged negligence in supplying it; the evidence on behalf of the defendant included that of a witness from the firm originally supplying the sardines to the effect that only sardines of good quality were supplied by them to the restaurant, and also that they were responsible for the supply of similar goods to various clubs and restaurants, whence no complaints had been received. Friends who accompanied the plaintiff to the restaurant and partook of sardines also stated that they had been made ill There was medical evidence to the effect that the plaintiff's condition had been consistent with ptomaine poisoning, but the opinion expressed by the medical practitioner who saw him [illegible] that he then was suffering from [illegible] questions were submitted to the [illegible] below. "Were the sardines [illegible] onably fit for human consumption?"—"No." "Was the illness of the plaintiff caused by such unfitness?"—"Yes." "Was the defendant negligent in supplying the sardines?"—"No." "What damages?"—"£26 10s." Upon these answers a verdict was entered for the plaintiff for the sum named, in respect of the breach of warranty, a certificate that the case was fit to be brought in the

High Court being refused. This refers to the amount of the damages, which in the absence of such certificate would entitle the plaintiff to costs on the county court scale only. Mr. Justice Horridge expressed the opinion that the case was one which a county court judge might have tried. The sub-section of the Sale of Goods Act referred to in this case may be of interest, as it is often brought forward in cases where dealers in food are sued in respect of the defective quality of goods supplied. It will be observed that the concluding words prevent the possibility of applying the section to the sale of quack medicines by retail dealers. "Where the buyer, expressly or by implication, makes known to the seller the particular purpose for which the goods are required, so as to show that the buyer relies on the seller's skill and judgment, and the goods are of a description which it is in the course of the seller's business to supply (whether he be the manufacturer or not), there is an implied condition that the goods shall be reasonably fit for such purpose, provided that in the case of a contract for the sale of a specified article under its patent or other trade name, there is no implied condition as to its fitness for any particular purpose."

Fleet v. *Johnson and Sons: Workmen's Compensation.*

In a recent case under the Workmen's Compensation Act, 1906, before the Court of Appeal, the county court judge had made an award in favour of the dependents of a deceased workman, a bricklayer. He had returned home with a sore on the back of his thumb on a certain date, and a month later had died from blood-poisoning after an abscess had developed in his armpit. The initial injury was one which might naturally be incurred in using a hammer and chisel as he had been using them, and the medical evidence was to the effect that the injury to the thumb might well have given rise to the blood-poisoning from which death took place, the medical witness before the arbitrator also making the admission in cross-examination that a dirty condition of the armpit might have caused the abscess referred to. There was, however, no evidence of such a condition having in fact existed. The medical witness had stated that as a matter of scientific opinion he had no doubt that the blood poisoning had been set up through the injury to the thumb. The Court of Appeal held that the county court judge was justified in accepting the medical evidence and in ascribing death to the accident alleged. The Master of the Rolls, who delivered the judgment of the court, laid emphasis again upon the point that the question was one not of law but of fact, as to which the court would not interfere with the finding of the county court judge unless he was shown to have misdirected himself. It was for applicants for compensation to establish their case, but it was not necessary for them to bring witnesses who had actually seen the alleged accident take place. They might prove facts from which it might be inferred. It must be proved where death ensued that it was due to the accident, but it need not be shown that it was a result to be expected. It might be an improbable and unexpected result, but that did not matter if it was shown that the accident did in fact have death as its consequence. The two questions which the county court judge had to answer, and which in the opinion of the Court of Appeal he had evidence before him to justify him in answering them as he had done, were: Did the workman meet with the alleged accident while he was at work? and, secondly, Did death result from that accident? The case may be taken as an example of the nature of the facts to be established not infrequently under the Workmen's Compensation Act, and of the points to which medical evidence may have to be directed when deaths of the kind described take place.

The Sale of Hypnotic Drugs.

At the February meeting of the council of the Pharmaceutical Society a resolution was carried in the following terms:—

> That by virtue and in exercise of the powers vested in the council of the Pharmaceutical Society of Great Britain by Section 2 of the Pharmacy Act, 1868, as modified by Section 1 of the Poisons and Pharmacy Act, 1908, the said council does hereby resolve and declare as follows:—That [illegible] ought to be deemed a poison within the me[illegible] Act, 1868, as amended by the Poisons and P[illegible] ought to be deemed a poison in the second part of the Schedule of Poisons to that Act.

This resolution has been sent to the Privy Council for approval. Diethyl-barbituric acid is known under various trade names, the best known being veronal. In March last year the council of the Pharmaceutical Society recommended, in another form of words, the addition of diethyl-barbituric acid to the list of poisons, but this recommendation was not adopted; the new resolution was framed with the object of divesting the former resolution of points of controversy which it contained.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census, and whose aggregate population at the middle of this year is estimated at 17,852,764 persons, 9082 births and 5896 deaths were registered during the week ended Saturday, Feb. 8th. The annual rate of mortality in these towns, which had steadily increased from 15·4 to 17·3 per 1000 in the four preceding weeks, declined to 17·2 per 1000 in the week under notice. During the first six weeks of the current quarter the mean annual death-rate in these towns averaged 16·5, against a corresponding rate of 17·0 per 1000 recorded in London. The death-rates last week in the several towns ranged from 4·2 in Ilford, 8·6 in Gillingham, 9·8 in Wolverhampton, 10·0 in Ealing, 10·2 in East Ham, and 10·3 in Walthamstow to 24·7 in Wigan, 24·9 in Wakefield, 26·0 in South Shields, 26·4 in Bury, 30·9 in St. Helens, and 41·9 in Stockton-on-Tees.

The 5896 deaths from all causes in the 96 towns were 10 fewer than the number in the previous week, and included 445 which were referred to the principal epidemic diseases, against numbers declining from 526 to 430 in the three preceding weeks. Of these 445 deaths, 200 resulted from measles, 78 from whooping-cough, 75 from infantile diarrhœal diseases, 45 from diphtheria, 29 from scarlet fever, and 18 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·3, against 1·5 and 1·3 per 1000 in the two previous weeks. The deaths attributed to measles, which had been 277, 275, and 205 in the three preceding weeks, further declined to 200 last week, and caused the highest annual death-rates of 2·3 in Edmonton and in Sheffield, 2·4 in West Hartlepool, 2·8 in South Shields, 3·4 in Wigan, 3·8 in West Bromwich, 4·0 in Stockton-on-Tees, 4·2 in Acton, 5·2 in St. Helens, and 5·7 in Eastbourne. The deaths referred to whooping-cough, which had been 61, 81, and 66 in the three preceding weeks, rose to 78 last week, and included 37 in London and its suburban districts, 8 in Liverpool, and 3 in Bristol. The fatal cases of diarrhœa and enteritis (among infants under 2 years of age), which had declined from 87 to 65 in the three preceding weeks, rose to 75 last week; 27 deaths were registered in London, 7 in Birmingham, 7 in Liverpool, and 3 each in Stoke-on-Trent, in Manchester, and in Middlesbrough. The deaths attributed to diphtheria, which had been 59, 47, and 62 in the three preceding weeks, declined to 45 last week, of which number 8 occurred in London, 5 in Birmingham, 3 in Coventry, and 3 in Manchester. The deaths referred to scarlet fever, which had fallen from 32 to 17 in the four preceding weeks, rose to 29 last week; 7 deaths were recorded in London, 5 in Birmingham, 3 in Rhondda, 2 in Liverpool, and 2 in Preston. The fatal cases of enteric fever, which had averaged 15 in five preceding weeks, were 18 last week, and included 4 in London, 3 in Preston, and 2 in Liverpool.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospitals, which had steadily declined from 2112 to 1738 in the six preceding weeks, had further fallen to 1735 on Saturday last; 209 new cases of this disease were admitted during the week, against 204, 215, and 209 in the three preceding weeks. These hospitals also contained on Saturday last 962 cases of diphtheria, 804 of measles, 307 of whooping-cough, and 39 of enteric fever, but not one of small-pox. The 1499 deaths from all causes in London were 111 fewer than the number in the previous week, and were equal to an annual death-rate of 17·3 per 1000. The deaths referred to diseases of the respiratory system, which had steadily increased from 285 to 447 in the seven preceding weeks, declined to 373 last week, and were 172 below the number recorded in the corresponding week of last year

Of the 5896 deaths from all causes in the 96 towns last week, 183 resulted from various forms of violence and 426 were the subject of coroners' inquests The causes of 52 or 0 9 per cent, of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest All the causes of death last week were duly certified in Manchester, Leeds, Bristol, Bradford, Hull, Newcastle on-Tyne, Nottingham, Salford, and in 62 other smaller towns The 52 uncertified causes of death included 7 in Liverpool, 5 in Stoke on-Trent, 5 in Birmingham, 5 in Sheffield, and 3 in Barrow in Furness

HEALTH OF SCOTCH TOWNS

In the 16 largest Scotch towns, with an aggregate population estimated at 2,260,200 persons at the middle of this year, 1165 births and 900 deaths were registered during *the week ended Saturday, Feb 8th The annual rate of* mortality in these towns, which had increased from 17 3 to 20 2 in the four preceding weeks, rose to 20 8 per 1000 in the week under notice During the first six weeks of the current quarter the mean annual death rate in these Scotch towns averaged 19 1 against a corresponding rate of 16 5 per 1000 in the 96 large English towns Among the several Scotch towns the death rates last week ranged from 10 5 in Kilmarnock, 11 7 in Kirkcaldy, and 14 6 in Clydebank, to 24 9 in Falkirk, 25 3 in Perth, and 29 0 in Ayr

The 900 deaths from all causes were 26 in excess of the number in the previous week, and included 88 which were referred to the principal epidemic diseases, against 80 and 74 in the two preceding weeks Of these 88 deaths, 52 resulted from whooping cough, 12 from diphtheria, 10 from infantile diarrhoeal diseases, 5 from measles, 5 from scarlet fever, and 4 from enteric fever, but not one from small pox These 88 deaths from the principal epidemic diseases were equal *to an annual death rate of 2 0, against 1 3 per 1000* in the 96 large English towns The deaths attributed to whooping cough, which had steadily increased from 29 to 55 in the five preceding weeks, were 52 last week and included 34 in Glasgow, 7 in Edinburgh 4 in Leith, 2 in Aberdeen, and 2 in Motherwell The deaths referred to diphtheria, which had been 10, 13 and 6 in the three preceding weeks rose to 12 last week 4 deaths were registered in Aberdeen and 3 in Glasgow The fatal cases of diarrhoea and enteritis (among infants under two years of age), which had been 10, 20, and 5 in the three preceding weeks, rose to 10 last week, 4 of which occurred in Glasgow The 5 deaths from *measles, 3 of which were recorded in Glasgow were slightly* in excess of the average in recent weeks The 5 deaths referred to scarlet fever were equal to the average in the five preceding weeks, and comprised 3 in Glasgow and 2 in Coatbridge Of the 4 fatal cases of enteric fever, 2 occurred in Glasgow, 1 in Aberdeen, and 1 in Greenock

The deaths referred to diseases of the respiratory system in the 16 Scotch towns, which had steadily risen from 148 to 221 in the four preceding weeks, declined to 214 in the week under notice, 34 deaths were attributed to different forms of violence, against 27 and 31 in the two preceding weeks

HEALTH OF IRISH TOWNS

In the 27 town districts of Ireland with an aggregate population estimated at 1,199,180 persons at the middle of this year, 654 births and 481 deaths were registered during the week ended Saturday, Feb 8th The annual rate of mortality in these towns, which had declined from 22 2 to 20 4 per 1000 in the three preceding weeks, increased to 20 9 per 1000 in the week under notice During the first six weeks of the current quarter *the mean annual death rate* in these Irish towns averaged 21 3 per 1000, in the 96 large English towns the corresponding death rate did not exceed 16 5, while in the 16 Scotch towns it was equal to 19 1 per 1000 The annual death rate recorded in the several towns last week was equal to 17 7 in Dublin (against 17 3 in London and 22 2 in Glasgow), 23 2 in Belfast, 22 4 in Cork, 20 3 in Londonderry, 16 2 in Limerick, and 26 6 in Waterford, while in the remaining 21 smaller towns the mean rate was 22 4 per 1000

The 481 deaths from all causes in the 27 Irish towns were 11 in excess of the number in the previous week, and included 41 which were referred to the principal epidemic diseases, against numbers steadily declining from 53 to 30 in the four preceding weeks Of these 41 deaths, 18 resulted from measles, 9 from infantile diarrhoeal diseases, 5 from diphtheria 4 from whooping cough, 2 from scarlet fever, 2 *from enteric fever, and 1 from typhus, but not one from* small pox These 41 deaths from the principal epidemic diseases were equal to an annual death rate of 1 8 per *1000*, the death rate from these diseases in the 96 large English towns last week did not exceed 1 3, while in the 16 Scotch towns it was equal to 2 0 per 1000 The deaths attributed to measles, which had been 22 17, and 21 in the three preceding weeks, fell to 18 last week, and *included 14 in Belfast and* 2 in Newry The deaths of infants (under 2 years of age) referred to diarrhoea and enteritis, which had declined from 12 to 5 in the four preceding weeks, rose to 9 last week, 5 deaths occurred in Belfast and 2 in Dublin The 5 fatal cases of diphtheria *recorded last week were equal to the average in the five pre*ceding weeks, and comprised 4 in Belfast and 1 in Dublin The 4 deaths attributed to whooping cough last week, of which 2 were registered in Dublin, were slightly in excess of recent weekly numbers The 2 deaths referred to scarlet fever were recorded in Dublin and Wexford respectively, those to enteric fever in Dublin and Newry, and the fatal case of typhus in Galway

The deaths referred to diseases of the respiratory system, which had been 113 135 and 120 in the three preceding weeks, declined to 104 in the week under notice Of the 481 deaths from all causes 164, or 34 per cent, occurred in public institutions, and 16 resulted from different forms of violence The causes of 12 or 2 5 per cent, of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 96 large English towns the proportion of uncertified causes of death last week did not exceed 0 9 per cent

THE SERVICES

ROYAL NAVY MEDICAL SERVICE

THE following appointments have been notified —Fleet-Surgeon H Spicer to the *Cornwallis* Staff Surgeons S Roach to the *Devonshire*, and N B V Jacob to the *Roxburg* geons G A S Hamilton to the and A Fairley to the *Victory*,

Fleet Surgeon A S Gordon Bell has been placed on the retired list at his own request (dated Feb 1st, 1913)

ROYAL ARMY MEDICAL CORPS

The undermentioned Lieutenants to be Captains (dated Jan 31st, 1913) Gilbert H Dive, Lionel C Hayes Robert Gale, Alfred G Jones, Kenneth Comyn, Frederick R Laing, Arthur S Cane, John M Weddell, Charles M Nicol, Arthur P O Connor, Thomas H Dickson, Hugh G Robertson, Herbert V Stanley, Philip C Field Ronald M Davies, Richard C G Kinkead, Edward C Stoney, Theodore W Stallybrass and Victor P Hutchinson

The undermentioned Lieutenants are confirmed in their rank William B Laird, Frances R B Skrimshire Edward B Allnutt Harry C Todd, Maurice Burnett, Gilbert A Blake, Robert W Vint, Harold W L Allott, John Hare, Robert A Flood, Eric C Lang, Leopold T Poole, Thomas H Balfour, Reginald E Porter Hugh J S Shields Pierce M J Power, Edward V Whitby, Edmund U Russell, Norman W Stevens, Richard B Phillipps James C Sproule, George F Allison, Robert C Carlyle, John E Hepper, and Henry F Panton

Colonel C E Faunce has been selected for appointment as *Assistant Director of Medical Services to the Woolwich* District, in succession to Colonel R W Ford D S O

Brevet Colonel C H Melville, commanding the Military Hospital at Lucknow Cantonment, has been selected for the higher rate of pay under Article 317 of the Royal Warrant for Promotion

Lieutenant Colonel S Macdonald has been transferred from medical recruiting duties in the London District to the Southern Command ington
has been selected fo of the
Military Hospital at J J
Gerrard has taken up in the

embolism of the pulmonary artery, even in cases conducted with aseptic methods. This fact should lead to precaution as to the dietary of pregnant women, especially in the upper classes, who are sometimes over-nourished.

The tendency to viscosity of the blood is to be met by diminished use of animal food and increased use of fresh, especially green, vegetable food. Where the circulation is languid alcohol in some form is of much value. Milk should be sparingly used and diluted with sodium citrate and soft water. The use of ether as an anæsthetic may perhaps prove unadvisable in cases where a hyperinotic condition of the blood is suspected.—I am, Sir, yours faithfully,

Grosvenor-place, S.W., Feb. 10th, 1913. DYCE DUCKWORTH.

RESEARCHES IN COLOUR VISION.

To the Editor of THE LANCET.

SIR,—I have just been reading a book with the above title by Sir W. Abney with the greatest gratification. When a scientific man has striven for the greater part of his life, against the greatest opposition, to establish certain new principles, facts, and methods, it is very pleasing to find that a man who has been his chief opponent should, though rather late in the day, have adopted those methods.

For 24 years I have advocated certain methods of testing for colour-blindness based on my own theory of colour vision. I have insisted, in opposition to Sir W. Abney, that colour names were essential in any test, and that coloured lights should be used instead of coloured wools. The first test mentioned is the Holmgren wool test; to this two new test skeins have been added similar to those in my classification test. Sir. W. Abney writes: "If the examinee is asked to name some of the confusion colours, the giving of a wrong name to any of them will confirm what has probably been found out by the matches." The word "probably" is very significant. The next test mentioned is one by water-colour washes, in which squares of pale colours are named (see p. 105 of my book, "Colour Blindness and Colour Perception," International Scientific Series, 1891 and 1909). Sir W. Abney gives laboratory tests in which the examinee is asked to name portions of the spectrum in a similar manner to that described in my book, p. 111. The imperfect lantern test recommended by the Departmental Committee of the Board of Trade is described. This would have been a better copy of my lantern and more efficient if means for regulating the luminosity had been adopted. A test by simultaneous contrast is next mentioned. I was the first to point out that simultaneous contrast is more marked for the colour-blind than the normal-sighted (see my book, p. 270). My only regret is that Sir W. Abney has given two other methods—namely, matching yellow with a mixture of red and green and estimating the relative luminosities of red and green by means of the flicker method of photometry. Both of these are based on the trichromatic theory, and I have shown both to be erroneous, but only within the last few weeks; that is to say, a man who is so colour-blind as to confuse full red and full green may appear absolutely normal-sighted by these methods, whilst a normal-sighted person may appear colour-blind.

As Sir W. Abney states that his book is the substance of a large number of communications to the Royal Society, and I am unable to find the methods described by him in them with the exception of the two which I regard as erroneous, I think I may draw attention to one slight omission in that he has not mentioned my name throughout the book. I am, Sir, yours faithfully,

F. W. EDRIDGE-GREEN.

THE PATHOGENICITY AND VIRULENCE OF BACTERIA.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Feb. 8th, p. 413, it is stated by Dr. F. H. Thiele and Dr. Dennis Embleton that, anticipating our criticism, they took full precautions to guard themselves against error in their recently published experiments. A year ago we published charts which showed that the use of water collected from either the condensing drip or the collecting tank of the ordinary distilling apparatus leads to serious error in the study of experimental fever. This is due to the infection of both worm and tank that frequently occurs in consequence of the aspiration of infected air caused by cooling. We also showed that the use of filtered water introduces a further source of error owing to contamination of the filtrate with calcium and other salts if hardware filters are employed. Dr. Thiele and Dr. Embleton admit the use of the hardware filter and of water from the condensing drip in all their experiments, and it is therefore difficult to understand in what sense their precautions against error were complete. If, however, they will collect into sterile agar tubes 1 or 2 c.cm. of water direct from the condensing drips of a series of the distilling vessels in ordinary laboratory use, they will be able to see for themselves the percentage of tubes in which gross infection will have taken place. And if, further, they will add ammonium oxalate to water after passage through the Pasteur-Chamberland filter—which they apparently believe to be innocent of calcium—they will be able to confirm our observation that it contains calcium in considerable amount. After repetition of these two experiments they will, we feel sure, be the first to admit the accuracy of the demonstration we gave last March that water after filtration through hardware filters is no longer pure water, and that even unfiltered water when it fails to produce a fall of temperature when injected is also not pure water. As regards the use of the guinea-pig as a suitable animal in which to study experimental fever by repeated observation, the point of our remarks on the subject was that very inconstant temperatures had been found sometimes to occur in uninjected animals in spite of the fact that they had been kept for weeks on a constant and adequate food-supply. In view of this fact, study of an equally large number of animals will convince the most sceptical observer that this—the third source of error to which we referred—is one that cannot be ignored. We are, Sir, yours faithfully,

E. C. HORT.
The Lister Institute, Feb. 8th, 1913. W. J. PENFOLD.

AN INTERESTING EXHIBITION OF RAYNAUD'S PHENOMENA.

To the Editor of THE LANCET.

SIR,—The interesting article by Professor T. Wingate Todd in THE LANCET of August 10th, 1912, on The Vascular Symptoms in "Cervical" Rib, suggests that the following curious case may be of interest.

A B, a strong, healthy man, first came under observation in May, 1911. He is 45 years of age and married, a teetotaler, and has three healthy children, youngest 8 years; no history of syphilis, and has never had any illness. His occupation causes him to do a good deal of hammering with a heavy hammer. Complained first of "pins and needles" pains in the ulnar side of his right hand and of two inner fingers, severe enough to keep him awake at night. Liniments and the faradic current gave no relief. A small swelling about the centre of the ulnar side of the right forearm was explored for a foreign body, but nothing was found. The tingling pain soon spread to the radial side of the hand, and was accompanied by swelling and weakness of grasp. The reflexes, wrist and elbow jerk, were normal; cutaneous sensation to touch, pain, and temperature was diminished. Three months from the commencement of the attack the hand exhibited the milder phenomena characterising Raynaud's disease—viz., local syncope, especially after elevation and immersion in cold water, and local asphyxia after hanging the hand down. About this time a small swelling became manifest near the proximal end of the extensor secundi internodii pollicis tendon. This also was explored and nothing found. The patient was told to wear a thick glove and to avoid cold water. Owing to the severity of the pain small doses of anodynes were necessary to procure sleep. About this time it was noticed that the right subclavian pulse was very much more difficult to feel than on the left side, the brachial pulse was very feeble, and the radial and ulnar arteries imperceptible. Faradism having quite failed to give relief, early in 1912 galvanism was tried, with the approbation of Dr. W. Mitchell Stevens, of Cardiff, who took great interest in the case. The patient began with eight cells of a constant current battery of 24 dry cells, going on to 16 and using the method originally recommended by Raynaud and practised by Sir Thomas Barlow—that is, one electrode over the cervical spine, and the other in a basin of warm water in which the hand was immersed The patient, being desirous of saving his hand, persevered with this treatment, although many small burns occurred on the skin of the nape and upper arm from the strength of the current employed The vaso motor disturbances and the pain gradually lessened The grip strengthened, and the patient returned to duty in July, 1912, doing light work at first, and has now resumed his full work Dr. Stevens stated that the maximum blood pressure was 130 mm No tumour could be felt anywhere in the course of the arterial trunk of the affected limb Embolism appears out of the question, as his heart is perfectly healthy, and the symptoms commenced in the ulnar nerve Thrombosis also seems out of court on the same grounds; and the fact of recovery after the use of galvanism points to the phenomena being due to implication of the branch of the cervical sympathetic chain which controls the vascular supply of the upper limb

After reading Professor Wingate Todd's interesting cases, we naturally expected to find the shadow of a cervical rib in this case, but no trace of such a shadow was found Possibly in the cervical rib cases the rib is merely a predisposing cause, and some slight injury to the root of the neck is the exciting cause of the pseudo-Raynaud symptoms Obviously the abnormal rib has been present from birth, whereas the symptoms, instead of being congenital, appear in active adult manhood, when traumatism is likely to occur

I am, Sir, yours faithfully,

ARTIFICIAL RESPIRATION

To the Editor of THE LANCET

SIR,—One strongly deprecates the habit nowadays of going outside one's province This is an example, when an attempt is made to explain in the physical plane what has evidently taken place in the spiritual plane However, whatever has been paraphrased loosely from the received Hebrew *text is due to unskilfulness and arbitrariness* The powers, too, of the translators were limited The word in the Septuagint which is translated as child in the English version is *παιδάριον* This is a diminutive from *παῖς*, and means a young or little boy We may take it that the person was a child and not an adult In the same passage the same term *παιδάριον* is used of the servant, and in classical Greek it means a young slave The Verse 34 which has been quoted in your issue of Feb 1st is part of a paragraph The paragraph commences at Verse 18 *as follows*: "18 ¶And when the child was grown, it fell on a day, that he went out to his father to the reapers 19 And he said unto his father, My head, my head! And he said to a lad, Carry him to his mother 20 And when he had taken him, and brought him to his mother, he sat on her knees till noon, and then died" From this last Verse 20 some considerable period has elapsed before we come to the remarkable Verse 34, in which the child seems to have been revived by what Professor Leonard Hill would style "Elisha's method of artificia [illegible] fathom the nature [illegible] medical point of [illegible] side our definite range

I am, Sir, yours faithfully,
JOHN FREDK BRISCOE

Alton, Hants, Feb 8th, 1913

To the Editor of THE LANCET

SIR,—Since you published my letter in THE LANCET of Feb 8th in reply to Dr Leonard Hill I have discovered the following passage with reference to the matter in "The Diseases of the Bible," by Sir Risdon Bennett, M D, F R S, Ex President of the Royal College of Physicians (The Religious Tract Society, London, 1887).—

[illegible] when the child was [illegible] ather to the reapers [illegible] And he said to a lad, [illegible] *d taken him,* and [illegible] nees till noon, and [illegible] the bed of the man [illegible] nt out' This case [illegible] insolation and this exclamation, "My head, my head" is to be understood as intimating sudden severe pain [illegible] in instance of sudden [illegible] he brain) supervening [illegible] of sunstroke, all of [illegible] In the severer form, [illegible] are overwhelmed the [illegible] death may ensue rapidly. [illegible] fails, and the skin is cold. [illegible] prove so in the course of a [illegible] s after a period of reaction accompanied by symptoms of severe injury to the nervous system That death had actually occurred in this instance there can be no reasonable doubt A period of ten or twelve hours at least must have elapsed before the arrival of the prophet And it was not till [illegible]

I am, Sir, yours faithfully,
STARCHER.

SERUM TREATMENT IN MELÆNA NEONATORUM.

To the Editor of THE LANCET

SIR,—A reference is made in the Annotations in THE LANCET of Feb 8th, p 403, to serum treatment in cases of melæna neonatorum by Dr Franz Bearing on this subject, I referred to this method of treatment in some detail in a thesis which is reprinted in the last volume of the Guy's Hospital Reports (Vol LXVI, p 328) It is here shown that Welch and Nicholson, of Philadelphia, have had equally successful results in the treatment of these cases with normal human blood serum

WILSON TYSON, M D Cantab

Lowestoft, Feb 10th, 1913

THERAPEUTIC USE OF VACCINES IN TYPHOID FEVER

To the Editor of THE LANCET

SIR,—In THE LANCET for Jan 18th, p 184, under "Annotations," is a review of my paper in the *American Journal of the Medical Sciences* for October on the therapeutic use of vaccines in typhoid fever. I wish to thank you for the very careful, complete, and concise review you gave of this paper There is one mistake, however, evidently a typographical error, to which I would like to call attention In the twelfth line of the second column occurs this sentence "He begins with 500 millions, and at intervals of *14* days, as long as necessary, gives a dose increased by 100 millions" The sentence should read. "He begins with 500 millions, and at intervals of *four* days as long as necessary, gives a dose increased by 100 millions" I hope you will make this correction as the difference is very important Your review will be read by more people than will see the original paper

I am, Sir, yours faithfully,
J G CALLISON, M D.

New York, Jan 31st 1913

THE ORDER OF ST JOHN OF JERUSALEM.

To the Editor of THE LANCET

SIR,—On the last day of January the hand of death removed from amongst us three really distinguished men the Earl of Crawford, Admiral Sir F G D Bedford, and Lord Ilkeston The first was a scientist and a soldier, the second a naval administrator and a fighting sailor, *the third a* medical man and a politician The two first named were Knights of Grace of the Order of St John of Jerusalem in England; the last was not The practice of conferring the decorations of this Order upon naval and military officers, members of the peerage, and gentlemen with influential friends at Court, to the exclusion of those who have actually done something towards the relief of suffering and sickness, has been prevalent for a long time, but it is quite time that a reform should be instituted I am not unmindful of the fact that there are *a few medical men* who have received promotion to the higher ranks of the Order; but they form an insignificant minority, and even they have been thus honoured for social or military rather than professional eminence in most cases. Admiral Bedford was a G.C.B. and a G.C.M.G.; his fame would have been no whit less glorious had he never become a Knight of the Order of St. John. The best of private reasons may have led to his reception of the honour. Lord Crawford was a Fellow of the Royal Society and a Knight of the Thistle, the two distinctions which marked him out clearly as prominent in science and distinguished in rank. He, too, might well have remained outside the higher ranks of the Order. Lord Ilkeston, on the other hand, throughout many years of his long professional career, not only was a very able and industrious hospital physician and teacher, but also rendered notable unremunerated services to the medical profession as a Direct Representative on the General Medical Council, to the public health of Birmingham, and afterwards to that of the United Kingdom when he became Parliamentary Secretary to the Local Government Board. For such services to the State no better recognition could well be devised than the bestowal of one of the two Knighthoods of St. John of Jerusalem. Universities delighted to honour him with their degrees, and public work obtained for him an hereditary dignity, but (I believe) that the Knighthood of Grace was not for him. When the purpose and origin of the Order of St. John is remembered, surely it is evident that something is amiss with its administration at the present day. His Majesty the King is Sovereign Head and Patron of the Order (in England), and was Grand Prior when he was Prince of Wales. He is credited with the intention of reforming the present system of the distribution of honours and titles, and I trust that he will not omit the Order of St. John from the scope of his reforms.

I know, Sir, that much that has been good in the Order has been chronicled in your columns, but I venture none the less to ask publicity for the remarks of,

Yours faithfully,
DOUBTFUL.

Feb. 2nd, 1913.

CHEWING-GUM.

To the Editor of THE LANCET.

SIR,—A case having occurred recently in the North of England in which death was suspected to have been caused, to some extent at least, by the use of chewing-gum, it appeared to me advisable to have samples of this article analysed. The following is the gist of the report received: "The samples are free from poisonous metals and actively harmful ingredients. They are compounded of a vegetable gum, known as chicle gum, which is allied in its nature to guttapercha, with sugar and flavouring essences. The gum present in these samples to the extent of 17 to 25 per cent. is not actively poisonous or harmful chemically, but is quite insoluble and indigestible. The use of these chewing-gums by children especially who are likely to swallow the whole is much to be deprecated, and should be discouraged by all available means."

Before taking any further steps, I feel that I should have some definite evidence to put forward. If, therefore, any reader of THE LANCET has had experience of actual cases in which harmful results accrued from the use of these substances, I should take it as a great favour if he would communicate the facts to me.

I am, Sir, yours faithfully,
H. KERR,
Medical Officer of Health.

Health Department, Town Hall, Newcastle-upon-Tyne,
Feb. 12th, 1913.

THE AFTER-CARE ASSOCIATION.—This association for watching over poor persons discharged from asylums for the insane will hold its annual meeting at the Medical Society's Rooms, 11, Chandos-street, Cavendish-square, London, W., on Tuesday, Feb. 25th, at 2.45 P.M. Sir James Moody will preside, and after the usual business a paper, entitled "After-Care in Cases of Mental Disorder and the Desirability of Extending its Scope," will be read by Dr. C. Hubert Bond, a Commissioner in Lunacy, and this will be followed by a discussion.

CHOLERA AND WAR IN THE NEAR EAST.

(FROM THE BRITISH DELEGATE TO THE CONSTANTINOPLE BOARD OF HEALTH.)

Cholera in the Turkish Empire.

AN exceptional stress of work, caused directly and indirectly by the state of war, has prevented me from continuing the record of the cholera epidemic in this country since the date of my last letter (published in THE LANCET of Nov. 9th, 1912). The apprehensions then expressed have been only too fully realised. Once again the tragedy of a violent cholera epidemic attacking defeated and exhausted troops has been enacted, and the deadly results of this sinister combination have been still further heightened by the complete breakdown of such arrangements as existed for dealing with disease in the stricken army. The story, though the first events are no longer of recent occurrence, should be placed on record in the columns of THE LANCET.

Early in November cholera appeared among the troops at the Tchatalja lines. It spread like fire through stubble. For a while large numbers of sick and dying arrived by every train at the terminus of the railway in Stamboul, and the roads between Tchatalja and the city were credibly reported to be littered with the bodies of soldiers dying and dead from the disease. At the railway terminus itself some wooden barracks were converted into temporary hospitals or receiving rooms, whence the sick were drafted to the other hospitals or the principal mosques in Stamboul. The latter were rapidly filled to overflowing, and here it must be confessed that not only lack of organisation but also no little inhumanity contributed to the disastrous result. It is, no doubt, true that many of the men interned in the mosques—notably that of St. Sofia—were deserters, and so, perhaps, merited scant consideration from the military point of view; but the dictates of humanity should have saved them from the fate that many of them seem to have met there. To speak of St. Sofia alone—the mosque was at one time surrounded by armed troops, who prevented all communication with the outside, while the cholera-stricken men inside were, it is credibly stated, left without treatment and almost without food or care of any kind. The number of deaths in this mosque alone has been variously estimated at figures ranging from 700 to 1500. When, a little later, the building was evacuated and handed over to the Board of Health disinfectors the conditions were foul beyond words. The 10,000 square yards of matting which covered the floor were soaked with cholera discharges and littered with human excreta. Some six or seven layers of this matting were found—the lower layers were black putrescent shreds—showing that whenever new matting had been needed it had been simply laid down over the old. For eight or ten days a bonfire of this matting was burning night and day in the courtyard of the mosque, and it took over three weeks to cleanse and purify the soiled building. It may be mentioned, in passing, that the statement published in some papers, that inscriptions had been found on the floor of the mosque after it was laid bare, was incorrect; the floor is merely one of irregular and uneven stone slabs, without inscription of any kind. It is now re-covered with new matting, and many more years will probably elapse before it is again exposed.

Shortly after the appearance of cholera in the army an endeavour was made to protect the city by stopping all infected and suspected troops and those who had been in contact with them at St. Stefano—a station on the line some seven miles from the walls of Stamboul. For a while the sick and dying were left here without shelter or care of even the most rudimentary kind. Relief first came from a few heroic individuals, working solely from humane impulse and with almost no funds at their disposal, and it was not until later that some tents were put up, by the military and Red Crescent authorities, in the fields and open spaces in and around the village, and some attempt made at a hospital organisation. But it was long before anything deserving the name really existed, and in the meantime a second tragedy, in no way less harrowing than that of the mosques of Stamboul, had been enacted in the fields of St. Stefano.

The Privations of War.

It can never be known how many Turkish troops died from cholera, but there can be no doubt that the number was an exceedingly high one On the other hand, in the St Stefano camps among the cholera cases there were also many men suffering from dysenteric and diarrhœic disorders other than cholera while many thousands of medical and surgical cases of all kinds remained here for days and even weeks before being drafted into the hospitals of Constantinople Many of these suffered from great weakness and anæmia, due to privations, accompanied frequently by general anasarca and ascites, without albuminuria or other sign of kidney trouble Almost as numerous were cases of spontaneous gangrene of one or more extremities The total number of this latter class of case was extraordinarily large This condition was brought about by long exposure to wet and cold, to general malnutrition, and to lack of treatment at the onset Some ascribed it to the wearing of tight putties, and this certainly contributed to the result in many instances, but not only did some of the soldier patients not wear putties, but identical cases have occurred (the writer has one such under treatment at this moment) in civilian refugees who had never worn them

It is noteworthy that at the time these cases occurred the weather was in no sense exceptionally cold—it was before the frost and snow set in—and the condition, though resembling an extreme degree of frost bite, was caused by prolonged exposure to a chilly temperature and great wet, rather than to a short exposure to a very low temperature as in the case of true frost bite General malnutrition, privation, and the absence of all treatment also played their part, and the remarkably symmetrical character of the gangrene, when both feet were affected, also tends to show that the trouble was as much of central as of local origin The failure of the commissariat department of the Turkish army in this war has become notorious and some of the patients in the writer's temporary hospital for wounded have averred that it was no unusual thing to go for two or three days without food, while on one occasion one patient and his comrades were for seven days with no other food than grass and wild herbs

Cholera in Constantinople

It was inevitable that cholera should appear among the civil population of Constantinople shortly after it attacked the army The earliest cases were recognised on Nov 5th By Nov 18th 268 cases and 99 deaths had been registered, and the subsequent weekly returns have been as follows —

Week	ending	Nov	25th	347	cases,	193	deaths
,,	,,	Dec	2nd	302	,,	166	,,

,,	,,	,,	27th	4	,,	2	,,
,,	,,	Feb	1st	1	case,	0	death

The last case occurred on Jan 27th, and Constantinople has now been declared cholera-free The total number of cases has been put at 2515, and that of deaths at 1245 Of these a certain number, but by no means a large proportion of the whole, occurred among the refugees who for the last few months have flocked into the city It has been estimated that over 100,000 persons have fled into Constantinople from the towns and villages situated in Thrace and Macedonia They are mostly exceedingly poor, and not a few died on the journey to the capital But the rest are a remarkably hardy class, and the men have suffered little from illness in spite of their privations A considerable amount of illness has, however, prevailed among the women and children At present there is an unusual (but for this city not excessively high) total weekly mortality from small pox, and measles and scarlet fever are exceptionally prevalent Typhus does not seem as yet to have made its appearance and to judge from the records of the winter of 1877-8, when the city was similarly crowded with refugees owing to the Russo Turkish war, the situation to day is, from a public health point of view, very much more favourable than it was then

Constantinople during the Russo Turkish War

At that time small pox, typhus, and other diseases decimated the refugees A valuable report on the conditions which then prevailed still exists, from which it may be gathered that they were at their worst in the months of March and April, so it is, of course, too early yet to make a final comparison between the two epochs At that time, in St Sofia alone, 7000 refugees were placed, and of these more than half died In a school at Ak Serai only 250 survived out of a total of 650 interned there, and elsewhere the same terrible ratio of mortality was maintained The doctors, nurses, and lay helpers suffered very seriously from typhus and other diseases contracted from the refugees But so far, in the present winter, in spite of the presence of cholera which was then absent, there has been no such catastrophe, though it must be confessed that, should the war continue (as seems inevitable at this moment), there are all the materials for a repetition of the events of 35 years ago. Even now there has been a very considerable mortality among refugees on their trek to this city, and also in less favoured towns, such as Salonica, and in the various districts of Asia Minor to which they have been, and still are being, transferred in large numbers

The measures taken to control the cholera epidemic in this city have been fairly adequate A large sum of money was voted by special decision of the Board of Health (whose funds are not primarily intended for such internal measures) to supplement the measures taken by the municipal and military authorities Cholera hospitals were opened in various parts of the town, squads of disinfectors were organised in all the municipal quarters, and a large additional medical and subaltern staff was engaged, and at no time could it be said that the epidemic was out of hand and beyond the control of the combined authorities

Cholera in the Provinces

In the provinces the following figures have been registered in continuation of those furnished in my last letter .—

Week	ending	Oct	9th			66	cases,	101	deaths.
,,	,,	,,	16th			33	,,	89	,,
From	Oct	16th	to	Oct	29th	72	,,	116	,,
,,	,,	29th	,,	Nov	8th	95	,,	176	,,
,,	Nov	9th	,,	,,	16th	84	,,	82	,,
,,	,,	16th	,,	,,	23rd	160	,,	218	,,
,,	,,	24th	,,	Dec	2nd	44	,,	47	,,
,,	Dec	3rd	,,	,,	11th	61	,,	3055	,,

Since the last named date no further bulletin has been issued During the first weeks covered by the table the disease was confined to various parts of Asia Minor and Northern Syria, including serious outbreaks in Aleppo and Damascus, and smaller ones in Baalbek, Alexandretta, and other towns The returns were (as usual) very incomplete, and only towards the end included the figures for Mecca and Medina As stated in my last letter, cholera broke out in the Hedjaz towards the end of September It had before that appeared among the pilgrims of several pilgrim ships performing quarantine at the Camaran lazaret. By Oct 5th the disease had reached Medina, imported by caravans from Mecca It continued to cause a moderate degree of mortality among the pilgrims until the fetes of Kurban Bairam began (on Nov 20th), and then, when the agglomeration of pilgrims was at its highest, the figures suddenly rose, and for a week or more from 400 to 500 deaths daily were registered among the pilgrims at Mecca at Mina, and Arafat, and on the road between these places The total number of cases or deaths has never been ascertained exactly, but the mortality has been estimated at something between 5000 and 9000 The disease appeared in Jeddah, with the returning pilgrims, on Nov 25th, for a few days it caused over 50 deaths a day here, but the outbreak did not last long, and appears to have been over by the middle of December after causing some 400 or 500 deaths

A considerable number of imported cases of the disease were seen at the Tor Lazaret among pilgrims returning northwards, but fortunately the infection did not pass the Suez Canal nor was it carried by the Hedjaz Railway from Medina to Damascus and the Syrian towns This was no doubt partly due to the measures taken at the lazarets of Tor and Tebuk, and partly to the fact that the season of returning pilgrimage now falls in the winter months The limitation of this outbreak of cholera, which was produced by a virus newly imported from the homes of the disease in India and the Dutch Indies, to the Hedjaz and the basin of the Red Sea was an exceedingly fortunate fact There can, I think, be little doubt that the ravages of cholera among the Turkish troops above described were due to a cholera microbe which had been for many years in Europe, and had lost some of its virulence in that period; and that, disastrous as were the results it produced, they would have been very much more so had a cholera germ newly imported from India or the Far East been introduced among the exhausted and famished men of the defeated Turkish army.

It has to be added that, at the moment of writing, large numbers of cases of diarrhœic disorders are under treatment in the camp hospitals at St. Stefano, and it is more than suspected that cholera exists among them. With the renewal of the war (which now appears inevitable, if it has not already begun) there must be serious apprehensions of a fresh outbreak of the disease in the Turkish and perhaps in both armies.

Cholera in Odessa.

Quite recently a few cases of cholera were reported from Odessa. On Jan. 8th an inhabitant of the town, a woman, was admitted to the municipal hospital suffering from the disease (bacteriologically confirmed), and died the next day. Between that date and Jan. 21st 4 more cases of the disease occurred; no further cases have been reported since the last-named date.

Constantinople, Feb. 4th.

THE ALL-INDIA SANITARY CONFERENCE.

(From our own Correspondents.)

Introductory.

The value of congresses and conferences in promoting knowledge and circulating new ideas is not universally accepted, although it is acknowledged by many. The practical results rarely realise the theoretical ideal. Some say they are overdone and that, although they bring together those who are willing and able to give their time to such methods of education, no real work is ever done and little practical good results.

The recent All-India Sanitary Conference, which took place in Madras from Nov. 11th to 15th, 1912, should become an annual function, for it has for its object the discussion of all sanitary questions in India. The importance of these has lately received much attention from the Indian Government, and by bringing together the flower of Indian sanitary experts opportunity is given for conferring on the many sanitary problems which must be dealt with in this country. The recent Congress included some 76 delegates nominated by the various Governments and representing all classes and all branches of sanitary science —besides some delegates whose position on the Conference it is difficult to understand; but it lacked that element of outspoken discussion of Western Countries, or rather it was overshadowed by the official element which pervaded the assembly. No doubt in India this, much as it is to be regretted, is difficult to avoid, for a spontaneous conference of scientists is impossible in India without the financial assistance and support of Government. The municipalities themselves would be unable to organise any such assembly, nor do any societies or institutes exist which are capable of doing so. The annual congresses of the British Association, different sanitary institutions, the British Medical Association, and other such organisations, meet under different conditions.

The Government of India, with the coöperation of the various Governments of the Presidencies, organised the recent Conference, and did it exceedingly well. The President, Sir Harcourt Butler, I.C.S., and his secretary, the Hon. Mr. Ludovic Porter, I.C.S., assisted by the Director-General of the Indian Medical Service, Sir C. Pardey Lukis, I.M.S., Surgeon-General W. B. Bannerman, I.M.S., of the Madras Presidency, the Sanitary Commissioner to the Government of India, Major J. C. Robertson, I.M.S., and the Sanitary Commissioner for the Madras Presidency, Captain W. A. Justice, I.M.S., with two or three Members of Council and several members of the Indian Civil Service lent an official air to proceedings that were interesting throughout. The majority of the delegates held Government posts, sanitary, medical, or engineering, and these, with a sprinkling of Indian medical men (appointed for reasons possibly well known to the various Governments, but difficult to understand from the standpoint of sanitary science), and, with the health officers and sanitary engineers of the larger cities of India, made up an assembly which should be capable of advising their Governments on the sanitary problems of the day. But they were more or less compelled to take an official view, and many questions which would in England be dealt with in an open and free discussion did not receive the consideration they deserve, and the sanitary commissioners or the sanitary engineers being Government officials could not break away through red tape for fear of offending the higher authority; while, on the other hand, every consideration was given to those representatives whose position as delegates it is difficult to recognise. However, there can be no two opinions as to the value of the work done at the Madras Conference, or the impetus it will give to sanitary science in India. The papers read, or taken as read, will amply repay perusal, but too much was attempted, and the delegates were flooded with literature and talk which will take much time for digestion. The immense amount of matter circulated could barely be glanced through, and papers containing questions of most vital importance were introduced and discussed without having been read by the delegates. There is much room for improvement in this direction, and the next Conference will no doubt be organised to remedy this.

In Sir Harcourt Butler the Conference had a most urbane and capable President, while Mr. Ludovic Porter carried out his onerous duties with tact and geniality. Sir Pardey Lukis presided at the Malaria Conference with much skill and forbearance, while his knowledge of the subject and his explicit statements much facilitated the work.

The strenuous duties of organising the assembly and providing conveyances, accommodation, and refreshment, and supplying the delegates with the papers printed and corrected, devolved on Major Robertson, Captain A. G. McKendrick, I.M.S., and Captain Justice, who performed their duties in a manner that elicited the approval of everyone, while the officials of Madras contributed in no small degree to the success of the Conference by providing interesting excursions and investigations into the many excellent sanitary arrangements of the city. The hospitality of the organisers of the Conference and His Excellency the Governor, and the Director-General and the officers of the Indian Medical Service, and the people of Madras was profuse, and the delegates who attended the Conference will look back with pleasure and profit to the All-India Conference of 1912.

The President's Address.

The Conference was opened by Sir **Harcourt Butler** in an able and brief address, welcoming the delegates, and pointing out how much importance was attached to that Conference by the Government of India. He said that the union of education and sanitation under the same department was no accident, since people must be educated to appreciate the objects of hygiene and sanitation. There were signs, he said, of a sanitary awakening in India. The establishments of the revived post of Sanitary Commissioner proved this, while to the Director-General of the Indian Medical Service had been allotted the bacteriological and research work to avoid its divorce from medical practice. A progressive policy of decentralisation was being followed. Eight additional deputy sanitary commissioners were being created, for which appointments Indians possessing the necessary qualifications, as well as officers of the Indian Medical Service, would be eligible. He referred to the work on cholera and kala-azar conducted by selected medical officers, to the stegomyia surveys, and to the purpose to follow these up with inquiries into relapsing fever, elephantiasis, dysentery, and various types of pneumonia.

Town Planning.

Mr. E. G. **Turner**, I.C.S., the town planning expert of the Government of Bombay, explained how those methods are to be adopted in the suburbs of the city.

In the afternoon Mr. J. P. **Orr**, I.C.S., chairman of the Improvement Trust, Bombay, read an interesting, if somewhat lengthy, paper on Light and Air in Dwellings in Bombay, in which he spoke of the work of the Improvement Trust and his proposals to deal with insanitary houses.

After some remarks on town improvement in Lucknow by the Hon. Rai **Ganga Prasad Varma** Bahadur, a paper on the Housing of the Working Classes in Large Cities in India was read by Dr. J. A. TURNER, and was followed by other papers dealing with building by-laws and various town improvements and congested areas, and the necessity for more stringent laws and by-laws.

After some discussion on the various papers read, resolutions were passed recommending the introduction, on modern lines, of town planning schemes, and relief of congested areas, and the adoption of provision on the lines of the English Housing of the Working Classes Acts, 1890 and 1909, adapted to local conditions and the habits of the people, and suggesting as a measure of demonstration and education that model towns should be constructed on these lines.

The importance of the questions which came before the Conference on the first day cannot be exaggerated, but to what practical issue these resolutions will lead it is very difficult to say. It was pointed out that the building by-laws of Bombay were defective in many ways, while those of Calcutta were fairly satisfactory. In the former city the existence of overcrowded and insanitary areas is one of the chief factors in the sanitary condition of the city, while in other cities of India the overcrowded areas are small and easily improved, as they are not comprised of high, many-storeyed, overcrowded buildings as in Bombay.

On the second day arrangements were made to show the delegates the sanitary engineering sights of Madras and the interesting sewage disposal and water-supply works, under the direction of Mr. J. W. Madeley and Mr. E. P. Richards, engineers to the Madras municipality.

Plague.

Papers on Preventive Measures, by Lieutenant-Colonel S. BROWNING SMITH, I.M.S., and Captain W. C. ROSS, I.M.S.; on Rat Destruction, by Major W. GLEN LISTON, I.M.S.; on the Spread of Plague by the Grain Trade, by Captain F. NORMAN WHITE, I.M.S.; on Antiplague Vaccine, by Captain W. D. H. STEVENSON, I.M.S.; on Plague in Madras Presidency, by Captain TAYLOR, I.M.S.; on the Annual Reappearance of Plague, by Lieutenant-Colonel BROWNING SMITH; and on the Carrying over of Plague Infection during the Non-epidemic Season, by Captain J. C. G. KUNHARDT, I.M.S., were read and discussed.

Resolutions were passed to the effect that an encouraging advance in the knowledge of the etiology and epidemiology of plague has taken place; that the public should be strongly impressed as to the importance of the rat as a factor in the causation of this disease; that preventive measures should be pressed during non-epidemic periods; and that grain stores were a source of danger.

Travelling Dispensaries.

Travelling dispensaries formed the subject of papers by Surgeon-General BANNERMAN and Captain H. ROSS, I.M.S., and led to some discussion, with the result that a resolution was passed advocating their adoption.

Water-supply.

A whole day was taken up with this very important subject. Mr. CURTIS, I.C.S., Commissioner, C.D., came from Poona to explain the financial position of the Government of Bombay with regard to the improvement of the water-supplies of the Presidency. Major W. W. CLEMESHA, I.M.S., read three papers respectively, Silt Removal in the Hooghly, Mechanical Filters, and the Bacteriological Standard of Purity. Dr. F. MAITLAND GIBSON, Assistant-Surgeon E. C. R. FOX, and Rai KAILAS CHANDRA BOSE Bahadur, C.I.E., dealt with the chemical and bacteriological treatment of water; Captain C. L. DUNN, I.M.S., Mr. C. H. WEST, and Mr. J. M. LACEY discussed the filtration of water; while Messrs. MILLER BROWNLIE and NANJUNDAYYA BELVADI explained the system of the working of tube and artesian wells.

Discussing filters, Major CLEMESHA said that pressure filters gave very poor results from a bacteriological point of view, and could not be relied on to make a polluted water safe. Gravity filters gave very good results.—Mr. MADELEY disagreed with Major Clemesha that the initial cost of rapid sand filters was considerably less than slow sand filters; the relative cost, he said, depended largely on the cost of the land available and on cost of materials.—Dr. A. G. NEWELL pointed out that all the tests had been done with only one type of mechanical filter; that it was not true that the Jewell filter gave the dose of chemicals automatically, though it was true of the Paterson filter; and that the wash water should be sometimes as high as 20 per cent. of the total output of the water at once put the filter out of the range of practical politics.—Mr. DISNEY, however, said that Major Clemesha had over-estimated the quar[illegible] Jewell gravity filters. The [illegible] proper tests under equal [illegible] Jewell, the Paterson, and Mather and Platt's filters.

In his paper on Bacteriological Standards of Purity, Major CLEMESHA promulgated an additional test, while the conclusion might be drawn from Dr. MAITLAND GIBSON'S interesting paper on the Analysis of Potable Waters in the Tropics that on the whole we are not any further advanced in this question, especially as regards Indian waters.

In the afternoon a visit was made to the King Institute at Guindy, where Dr. MAITLAND GIBSON, Captain W. S. PATTON, I.M.S., and Captain F. W. CRAGG, I.M.S., gave most interest-[illegible] Vaccine [illegible] l a paper [illegible] MACKIE, I.M.S.—The Analysis of Water by Dr. GIBSON proved also of great interest to the delegates, while the various filter beds and model sewage disposal works were inspected by the delegates interested in those branches of sanitary science.—The hospitality of Mr. Justice Gibson and Mrs. Gibson, in the grounds of the institute, proved a delightful interlude to the strenuous work of the delegates.

In the early hours of the fourth day the waterworks were inspected, and in the forenoon the section broke up into two subdivisions. In one, cholera, dysentery, and diarrhœa, and papers on sewage disposal, &c., were dealt with. In the other, tuberculosis, fever, and relapsing fever were discussed.

Cholera, Dysentery, and Tuberculosis.

Major E. D. W. GREY, I.M.S., read four papers dealing with the cholera vibrio in the biliary passages, cholera convalescents and contacts, epidemics of cholera caused by a carrier, and on disinfection in cholera. Papers were also read by Captain T. H. GLOSTER, I.M.S., on the Bacteriology of Cholera from investigations made in Bombay; by Captain W. C. Ross on the Epidemiology of Cholera, in which he somewhat discounted the importance of water carriage in the spread of cholera; by Major S. A. HARRISS, I.M.S., on the Effect of Pipe-water Supplies on the Reduction of Cholera; Methods used in Bombay Presidency for Checking the Spread of Cholera in Urban Areas, by Major H. A. FORBES KNAPTON, I.M.S.; on Methods of Treating Cholera Outbreaks in the United Provinces, by Captain DUNN; and on the Bacteriology of the Cholera Vibrio and its Relation to the Spread of the Disease from the Point of View of the Health Officer, by Dr. TURNER. All these papers provided an immense amount of useful and interesting matter for discussion. With the material at the disposal of the bacteriologists of India, and with the improved laboratory technique, it is much to be regretted that some more definite statements were not forthcoming.

Resolutions were passed that there is strong evidence to show that in India, in addition to contaminated water, the four following factors are of great importance in the spread of this disease: (*a*) Convalescents dischaıged while still infected; (*b*) healthy persons who have been in contact with cholera cases, and have acquired the infection without showing any signs of the disease, but who are excreting cholera vibrios in their stools; (*c*) flies; and (*d*) the personal habits of the people

Dysentery was ably dealt with and discussed by Major W. F. HARVEY, I.M.S., Captain J. CUNNINGHAM, I.M.S., Captain J. MORRISON, I.M.S., Captain A. W. GREIG, I.M.S., and others.

The resolution regarding dysentery was purely negative, and recommended a fresh start in the investigation.

Tuberculosis especially gave rise to an interesting debate. Dr. P. S. CHANDRA SEKHAR read a paper on the Prevention of Tuberculosis in Madras, and Lieutenant C. J. FOX, I.S.M.D., one on Tuberculosis in its Relation to Public Health. In the discussion that followed Dr. NEWELL said there were three stages of the disease to be considered for preventive action. In the implantation stage in early childhood it was necessary to improve the ventilation of schools and homes, and the relief of congested areas. Expensive measures were not a necessity; open sheds with corrugated roofs could be used in place of the present unhealthy type of schools inside cities. The next stage was the earliest period at which it could be diagnosed. Here tuberculin dispensaries were recommended. The country was not ripe for sanatoria. The homes of the people should be tackled first. He regarded compulsory notification from medical men as essential.—Major GRAHAM said that in the United Provinces the sanatorium in the Kumaon Hills had to refuse many applicants for admission. He considered that it would be wrong in the present stage of our knowledge to introduce dispensaries wholesale, as little supervision would be given.—Dr. G. J. RUTHERFORD said that a dispensary and a sanatorium were being started in Ceylon. Notification was not compulsory in Ceylon, but was so in Colombo.—Rai Bahadur KAILAS CHANDRA BOSE, C.I.E., regretted that the public did not call more for both sanatoriums and dispensaries.—Dr. C. A. BENTLEY stated that his experience in Bengal showed that 5 to 10 per cent. of the mortality in rural areas was from phthisis. He thought many cases came to towns from rural areas, and so there was a difficulty to get these cases early. Hence he doubted the utility of sanatoriums.—Dr. NEWELL referred to the use of cattle dung in flooring as a dangerous element.

Regarding tuberculosis it was agreed that a thorough and full inquiry should be made into the incidence of the disease in India, and the usual measures were suggested, including improvement in general sanitation, opening up of congested areas, light and air, the promotion of antituberculosis societies, tuberculin dispensaries, control of milk supplies, and compulsory investigation of the disease in large towns.

Mediterranean Fever.

Major HARVEY read a paper, by Captains PATTERSON and BROWN, I.M.S., on Reflections and Proposals Resulting from an Inquiry into Epidemics of Malta Fever occurring in the 37th Lancers and 10th Lancers in India. The paper dealt with three distinct outbreaks, and raised the necessity for further investigation into the prevalence of the disease in India, its cause, and best means of detection and prevention.—Captain F. P. MACKIE, I.M.S., agreed with the authors' views, and said the disease was not readily recognised. He knew of one epidemic regarded by one officer as beri-beri and another as kala-azar, which on investigation by the Sleeping Sickness Commission was proved to be Malta fever.—Dr. NEWELL said that Malta fever definitely existed in Lahore, and goats examined by a local Indian Medical Service officer were found to be infected. Goats were often kept inside houses in cold weather, and it was probable that their urine was infected.—Dr. BENTLEY said that kala-azar often resembled Malta fever. An undulant fever was seen in many cases of kala-azar.—Major P. N. O'G. LALOR, I.M.S., invited attention to a peculiar form of fever in Burma in which the fever was distinctly undulant, and heavy perspiration with other symptoms suggested Malta fever.—Dr. KORKE said that in 56 cases of kala-azar he had seen in Madras none of them showed any signs of undulant fever.—Dr. BENTLEY replied that both perspiration and undulant fever were seen in many cases of kala-azar.

Enteric Fever.

Major E. D. W. GREIG, I.M.S., read a paper giving an account of the results obtained from the working of the recommendations of the Enteric Fever Research Committee of the Government of India.

(To be concluded.)

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Manchester Tuberculosis Scheme.

THE Manchester scheme for the treatment of tuberculosis has now practically reached its final form, though it has still to receive the sanction of the city council as well as the approval of the Insurance Commissioners and the Local Government Board. The scheme has been prepared by the tuberculosis subcommittee of the sanitary committee of the corporation. It includes the two units—dispensary and sanatorium. The dispensary is to be a receiving house and centre of diagnosis, a clearing house and a centre for observation, for curative treatment, for the examination of contacts, and for "after care," an information bureau, and an educational centre. The chief tuberculosis officer is to be independent of the medical officer of health in clinical matters, and is to have a salary of not less than £500, with assistants when necessary. As to the sanatorium, one bed is advised for every 5000 of the population, which would give Manchester about 150 beds. The incidence of phthisis is greater on Manchester than on the rest of the country in the ratio of 3 to 2. The scheme will embrace insured and uninsured persons, and will provide sanatorium accommodation with 412 beds. The annual cost of the scheme is estimated at £39,604. The Local Insurance Committee will have £15,000 a year, and it is proposed that £8000 of this sum be handed over to the corporation. Thus the annual expenditure will be £31,304 more than the income. Half of this will be paid by the Treasury, and half out of the rates, according to the provisions of the Act.

Manchester Royal Infirmary Annual Report.

From the annual report of the Manchester Royal Infirmary it is gathered that the aggregate number of cases of all kinds exceeds that for 1911. The board of management, in discussing the possible effect of the National Insurance Act upon voluntary hospitals, state that the work of obtaining new subscribers has been seriously interfered with. They are thankful, however, that the result of the year's work is a slight increase in annual subscriptions. If, however, the National Insurance Act had not been passed they do not doubt that the hospital would have gained a very substantial increase in the subscription list. One of their difficulties has been a widely spread belief that hospital treatment was included in the Act, and would be, or should be, provided at the cost of the State. They declare that the continued provision of hospitals is not merely a gratification of the collective philanthropy of the community, but an economic necessity. They also point out that special treatment for serious diseases of the eye, ear, throat, diseases of women, and for ailments needing X rays, and other treatment not provided for in the Act will be required as hitherto, while no curtailment of the out-patient work will arise in connexion with the uninsured poor. When the hospital was removed to the present site it was pointed out to the trustees that £12,000 in new annual subscriptions would be required to enable the institution to pay its way. In 1912 the total sum received in this way was £4024, so that there is still a deficit of £8000 a year in annual subscriptions. Nor is that all. A sum of £25,000 is required to build and equip the central branch for accidents in the city.

Colne Typhoid Epidemic.

Up to the present the cases of enteric fever at Colne number 68, with four deaths.

Feb. 10th.

BRISTOL AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

University of Bristol: Memorial to the late Chancellor; Honorary Degrees.

ON Feb. 7th the council of the University received a communication through the chairman, Mr. Lewis Fry, from the sons of the late Chancellor, Mr. Henry Overton Wills. Mr. G. A. Wills and Mr. H. H. Wills have offered £150,000 for the erection of a new block of buildings, which sum includes £20,000 endowment for upkeep; and Mr. Melville Wills offers £20,000 towards general endowment purposes. A committee was gratefully appointed to consider these offers. Mr. G. H. Oatley, the architect of the recently built wings of the University, has drawn up provisional plans. These, if accepted, will not merely constitute a very large addition to the University premises, but also will provide a commanding frontage on a main thoroughfare, and a tower which will be one of the most prominent features of the city. These buildings will be erected on the site now occupied by the premises recently evacuated by the Blind Asylum, and at present used for University libraries. They will contain the main administrative buildings, including the principal entrance, an assembly hall to seat 1200 persons, council room, registrar's department and general offices, the arts library, the medical library, and a considerable addition to the space available for teaching and student life, which also will be augmented by the fact that the premises now used for administration will once more become available for teaching purposes. The tower will be nearly 200 feet high, and as it will stand at the top of Park-street, the main thoroughfare leading from the city to Clifton, it will be a dominant feature of the streets of Bristol. Through its base, which will be 57 feet square, an entrance to the whole University will be provided, [illegible] ball. [illegible] comple [illegible] buted [illegible] It was Mr. Overton Wills's gift of £100,000 that brought the University into being, and this further gift will help to keep his memory green for future generations.—The controversy concerning the granting of honorary degrees on a large scale, as practised at the installation of Lord Haldane as Chancellor of the University of Bristol, has attained excessive proportions. Aspersions have also been thrown on the chairman of council, Mr. Lewis Fry, which are deeply resented not only by those who know from the inside the value of Mr. Fry's work for the University, but also by all his fellow-citizens. It has been further suggested that there is constant dissension between the council and the teaching staff; this has been repudiated by the Senate in a resolution forwarded to council. It is felt generally that the matter has been quite fully discussed, and that no useful purpose will be served by prolonging the controversy.

Bristol General Hospital and Insured Persons.

The committee of the Bristol General Hospital has given a lead, in a circular letter issued to the press and to all the subscribers, which will probably be followed by all the other local institutions in regard to the treatment of insured persons. It states the intention of the committee to act in harmony with the resolutions passed by the governors of St. Bartholomew's Hospital which will exclude from hospital treatment all insured persons suffering from such ailments as can be dealt with by the panel practitioner, while admitting urgent cases and cases in which a second opinion and special treatment are desirable. The letter gives as a reason for this decision the desire of the committee to use the funds of the hospital and the energies of the staff to meet such needs on the part of the sick poor as cannot be met in any other way. The new rules will come into force from the beginning of March.

Clifton Dispensary.

At the annual meeting of subscribers it was stated that during the past year 2730 cases had been admitted to treatment at the Clifton Dispensary, a small reduction on previous years. It was urged that money would still be needed in spite of the Insurance Act, since this does not yet provide for the treatment of the dependents of insured persons and others who are outside its scope. The committee has decided to exclude all insured persons from the benefits conferred by the dispensary. Notwithstanding this decision subscriptions are said to be coming in satisfactorily.

The Treatment of Tuberculosis in Bristol.

The Bristol health committee are taking steps to provide [illegible] ing a larger [illegible] by adding [illegible] r hospital. A few cases have already been treated at the latter institution, and their favourable progress has encouraged the committee to believe that good results will be secured when new and specially designed premises are available there. There is still some doubt as to the exact extent of additional accommodation required. Provision is being made for dispensary treatment. It is announced further that a voluntary committee has taken in hand the provision of open-air schools and other necessaries for the treatment of tuberculous school children. Land will be acquired at a nominal rent, thanks to the kindness of Lady Greville Smyth, and it is hoped that if funds are forthcoming the school may be begun in the summer of this year.

Bristol Insurance Committee.

The Insurance Committee is getting to work, and several matters of medical interest were dealt with at its last meeting. There have so far been 228 applications for sanatorium benefit: of these, 47 are receiving sanatorium treatment, 56 dispensary treatment, and 49 domiciliary treatment. The sum allotted by the Commissioners (£4300 per annum) is not nearly adequate; it was suggested that £8000 would be needed for the treatment of insured persons suffering from tuberculosis. The medical service subcommittee has been appointed; the five medical representatives are Mr. H. F. Devis, Dr. T. M. Carter, Mr. G. S. Page, Mr. T. A. Collinson, and Mr. G. Scott Williamson. Dr. Bertram M. H. Rogers has been appointed Medical Inspector at a retaining fee of £50 for three months.

The Exeter Infectious Diseases Hospital.

The Local Government Board has granted permission to the Exeter city council to borrow the sum of £15,190 for the purpose of the extension of the Infectious Diseases Hospital. The council has accepted a tender for the scheme, but owing to the increase in the cost of building materials it was found necessary to ask permission of the Local Government Board to borrow an additional £2360.

Medical Officer of Health for 40 Years.

The Taunton press has been drawing attention to the fact that Dr. Henry James Alford has held the appointment of medical officer of health for 40 years. Dr. Alford states that the population of Taunton in 1871 was 14,957; in 1911 it amounted to 22,563. The death-rate for the decade 1871 to 1881 was 21·2, and for the ten years ending 1911 the death-rate was 14·6 per 1000. In 1873 the inhabitants of Taunton obtained their water mostly from wells, many of which were polluted; at the present time the water company's reservoirs have storage capacity for 158,000,000 gallons.

Devon County Council and Tuberculosis.

The Central Tuberculosis Dispensary, which has been established by the Devon county council at Exeter, was formally opened on Feb. 3rd. The medical officer for the institution is Dr. H E Goulden, who was formerly school medical inspector for the Barnstaple district of Devonshire.

Death of Mr. George Mark Archibald Rudkin, L R.C.P. & S. Irel.

Mr. G. M. A. Rudkin died at his residence, 2, The Crescent, Teignmouth, Devon, on Jan. 28th. Mr. Rudkin, who qualified as L.R.C.P & S. Irel. in 1870, had been for more than 30 years in practice at Teignmouth, and at the time of his death was consulting surgeon to the Teignmouth Infirmary and to the convalescent home. He was medical officer to several friendly societies, and had been surgeon to the Oddfellows for 25 years. He took a great interest in all local matters connected with Teignmouth, and was president of the local literary society. Mr. Rudkin will be much missed in Teignmouth. His funeral took place on Feb. 1st, and the attendance included several members of the profession.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Scottish Poor-law Medical Officers' Association.

THE annual meeting of the Scottish Poor-law Medical Officers' Association was held at the St. Enoch Hotel, Glasgow, on Jan. 31st. The report for 1912 stated that in every case of retirement the outgoing medical officer had supplied all necessary information for the incoming officer, and that there had been no complaints of unjust treatment and no case of dismissal of an officer by his parish council. This improvement upon past years justified the formation of the association. Vacancies existed in 17 parishes, several of them appearing year after year, owing to isolation, inadequate income, and so forth. In one case of a parish without a medical officer a neighbouring practitioner found it absolutely necessary to look after several paupers, and rendered his account to the parish council, which, however, refused to pay it, as the inspector stated he gave no written instructions to the practitioner to attend. The medical man was advised not to attend paupers in future without an order, to send in his account again, and on refusal to acquaint the Local Government Board with the facts, and, failing satisfaction, to raise a small debt action in the sheriff's court. As nothing further has been heard the matter is probably settled. With regard to the difficulty in prognosis. The treatment has demonstrated with great regularity the curability of deep angiomas (certain of which were treated in conjunction with Dr. Barbarin), and also the frequent cure of superficial cancer. With regard to deep cancers, radium was used with a purely palliative aim, and its use was in most cases followed by a temporary amelioration. Nevertheless, the result obtained amounted practically to a cure in certain cases of deep cancer of the parotid, the neck, and the uterus, the retrogression of which from the clinical point of view has persisted for three or four years. In spite, however, of the favourable results in some deep malignant tumours, still the authors think that the most advantageous field for the employment of radium is as an accessory to proper operative measures.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Question of Foreign Medical Students in German Universities.

FOLLOWING the example set by the medical students of Halle, the Berlin medical students recently held a meeting to protest against the overcrowding of the lecture-rooms and clinics by foreign students. Delegates from Halle were present and gave a report of the state of the anti-foreign movement at other universities. The meeting then passed a resolution to the effect that foreign medical students should be allowed to register only a fortnight after the beginning of the lectures, and that the first three rows in every lecture-room should be reserved for German students. Foreign students should not be allowed to act as dressers and clinical clerks unless no German student was applying for the appointments in question; they should pay double fees for the lectures, and be admitted only in a certain proportion to the German students. They must have passed the German examen physicum or a similar one in their native country previously to being admitted to the clinics. These demands are obviously far from being reasonable, and are much more severe than the original demands of the students in the University of Halle, who, as has been mentioned in this column, for a time refused to attend lectures in the end of last year, but returned to their studies after the Christmas holidays. The Government has promised to stop to a certain degree the invasion of foreign students, but will certainly not consent to measures which practically amount to a total exclusion of foreigners.

Prussian Schools in Rural Districts.

At a recent meeting of the Society for School Hygiene Herr Ströde read a paper on schools in rural districts in Prussia regarded from a hygienic point of view. Herr Ströde, who is a teacher in a school of this description, said that remarkable progress had been made in the construction of school premises since 1895, when new regulations were issued, but that the older premises, which were, of course, in the majority, were unsatisfactory. The rooms were cleaned only twice a week, and that by the children themselves. The rooms were often used for public meetings in the evening, so that the next morning the air was foul with tobacco-smoke and dust. The supply of drinking water was also open to objection, as there were sometimes no wells and the water was kept in a bucket placed in the class-room. The drinking glasses were insufficient in number, so that several children had to use the same glass, a condition which was very favourable for the spread of infectious diseases. It was very undesirable that school children should be engaged in agricultural work. Before going to school in the morning they had often to feed the cattle, and after school to drive the cattle to pasture, and must then learn their home lessons lying on the ground. The results of school training under these circumstances were doubtful, especially as the classes were often overcrowded. Herr Ströde strongly recommended the appointment of school medical officers in country places on somewhat the same system as exists in England, the district medical officer of health having already too many duties to be able to supervise school hygiene also. He considered that teachers ought also to have some instruction in hygiene, and to inform the parents when the children's health was unsatisfactory.

Dr. Friedmann's Treatment of Tuberculosis.

As already stated in these columns, the success of Dr. Friedmann's treatment of tuberculosis has been greatly exaggerated in the lay press, especially in foreign countries. The warnings of the medical press, including THE LANCET, have apparently been unheeded. At the beginning of a recent meeting of the Berlin Medical Society Professor Bier made a statement explaining his position in reference to the subject. He said that in consequence of certain foreign newspapers having mentioned his name in connexion with Dr. Friedmann's treatment he was continually receiving letters, especially from America and Spain, inquiring whether the new treatment was really so efficacious as reported in the journals of those countries. Patients also sometimes came from distant places to be under his care while receiving the treatment, because they believed that he was convinced of its advantages. He wished, therefore, to state as his opinion that he had the impression that Dr. Friedmann's remedy had a certain action on tuberculosis, but that it was in no way more efficacious than other methods of treatment. He could as a surgeon only speak of external tuberculosis, but he mentioned that Dr. Friedmann had declined to treat severe cases which afterwards showed some improvement under other methods. He regarded it as very undesirable that a system of treatment which was not yet sufficiently tested, and had hitherto been only used by Dr. Friedmann himself, should be lauded in the foreign press as affording a sovereign remedy. If the remedy should eventually turn out to be inefficacious much harm would be done to German medical science and to the Berlin Medical Society by the publishing of uncontradicted statements asserting that the members of the society had expressed themselves in favour of the remedy. He hoped the journals which had reported that he had recommended Dr. Friedmann's treatment would also insert his present statement. One result of the publicity given to Dr Friedmann's views has been that the Socialist section of the Berlin town council moved that the mayor and magistrates should take steps to prevent patients in municipal hospitals and inmates of orphanages from being used for therapeutical experiments unless under the special responsibility of the chief physician and with the consent of the patients or their guardians. The supporters of the motion, which after some discussion was, however, withdrawn, took this action in consequence of a statement to the effect that Dr. Friedmann had given injections of living tubercle bacilli to children in one of the municipal orphan asylums.

Migratory Impulse in Children.

Some interesting facts connected with the migratory impulse in children were mentioned by Dr. Stier in a paper read at a recent meeting of the Society for Internal Medicine. He said that during the past three years he had seen no fewer than 120 children brought to the out-patients' department of the Charité Hospital because they had repeatedly run away from home. The motive which led them to behave in this way was, of course, not always the outcome of a morbid condition, and was frequently nothing more than a spirit of adventure. Whether a given case was a pathological one or not could be ascertained only by the history of the child and the circumstances surrounding the act. It was quite useless to ask the children as to their motives. Some writers on the subject alleged that epilepsy was frequently the cause of children running away from home, but in actual fact this condition was seldom found among them. In two cases only a post-epileptic feebleness of mind was present; seven other children had had epileptic fits but a connexion between the fits and the migratory impulse was very uncertain. Hysteria was also rare among the children. The majority belonged to the feeble-minded and psychopathic class. Some of them had been so much impressed by some event in the street, such as a procession or a military band passing along, that they simply forgot to return home, and under these circumstances might absent themselves for a considerable time. Some were very irritable, and in consequence of depressing conditions at home or in school were brought to a state of frenzy which prompted them to run away. Another group were labouring under hallucinations and delusions of fear. Ethical defects were present in a certain number, and it was sometimes difficult to determine whether these children were psychopathic or only the victims of neglect. In some the inclination to run away was caused by an irresistible impulse without any obvious cause. Dr. Stier said that he had seen two cases in which the impulse was hereditary through three generations, occurring always at the age of 12 years. The prognosis was not unfavourable provided the children were under constant control in an institution of some kind.

A Carrier of Enteric Fever Bacilli.

In an outbreak of enteric fever which recently occurred in the barracks of the regiment of railway pioneers in Hanau, near Frankfort, some of the men at first presented symptoms of bronchitis and atypical fever, but after a few days suffered from diarrhœa, and bacteriological examination showed the presence of enteric fever bacilli. The disease spread rapidly over the whole barracks. The cause of the epidemic was after careful inquiry traced to a woman employed in the kitchen; she had suffered from enteric fever a few years ago, and was now found to be still carrying the bacilli of that disease. It was ascertained that the infection had been conveyed by potato salad which she had prepared, and she was of course removed from the barracks. The total number of patients infected from this source was 226, of whom 14 died.

Feb. 10th.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS.)

Committees on Rural and Urban Sanitation.

THE attention of the people, both professional and lay, of the United States, and particularly of New York State and City, is being directed to hygienic and sanitary matters very much of late, partly through the medium of the medical and secular press. Committees have been appointed by the new Governor of the State to study the question of rural and urban sanitation, who are expected as a result of their investigations to formulate ways and means to remedy existing evils.

The Port of New York.

The attitude of Dr. O'Connell, the port medical officer, in declaring for a continuance of State control of the port of New York rather than for its transference to Federal authorities, is greatly to be regretted. Statistics disclose the great importance of New York as the principal port of entry for imports and immigration not only to the City and State of New York, but to the country at large. Federal control of quarantine has justified itself more and more whenever it has been tried, while local management has miserably failed in many ports because of local prejudices, notably San Francisco during the plague fright some years since.

Proposed Sanitary Regulation of Marriage.

A New York State Senator has introduced a Bill providing that on application for a licence to marry each party to the contract must present a certificate from a licensed practitioner showing freedom from disease due to immorality. This measure has in principle been advocated by medical associations, but it is hardly specific enough to have the desired preventive effect. No such legislation is really likely to be of practical good yet, but this measure, to be logical, should be made broader by excluding also conditions [illegible] esults of matrimonial alliances. [illegible] local boards of health so as to [illegible] who would naturally be the one [illegible] to protect the family, and also would prevent hasty approvals without careful examination into the history, and allow of an examination by those less likely to be influenced by association or otherwise.

The Society of Medical Economics.

A new society of medical men called The American Society of Medical Economics has been established to devote its attention to questions bearing upon the economics of the practice of medicine. It will seek to protect the public against ignorant, improper, and corrupt legislation, medical frauds, substitution, drug store dispensing, the sale of impure drugs and foods, as well as all forms of quackery.

Restriction of the Sale of Cocaine in New York.

A new Bill is to be presented to the New York Legislature making the sale or possession of cocaine by an unlicensed person in New York City a felony, punishable by seven years' imprisonment. The Bill provides that the possession of cocaine by a licensed pharmacist shall be limited to 5 ounces at any one time; that the chemist shall not sell the drug in flakes or crystals, but must dispose of it in a solution or ointment of not more than 4 per cent., and keep a record of all sales; that prescriptions containing cocaine shall not be refilled; and that no sale of more than 1 ounce shall be made to any one person by the pharmacist.

A Filthy Practice.

The Buffalo (New York) Health Department has been making [illegible] condition of finger bowls in [illegible] Brass finger bowls are declared [illegible] has been made that they spread disease be[illegible] them thoroughly. [illegible] that waiters are [illegible] has been previously used. As many persons wash their lips, as well as fingers, in such bowls. the danger is obvious. It needs also to be insisted on in public eating-places that waiters shall not be allowed to sneeze in such places without protecting their nose and mouth with their handkerchiefs, instead of with the napkins which they are continually using.

Society for the Advancement of Clinical Study.

There has recently been organised in New York City the Society for the Advancement of Clinical Study, which will maintain a bureau of information where resident and visiting physicians can obtain definite information regarding the clinical facilities of the hospitals and laboratories of the city. A bulletin board has been installed at the Academy of Medicine, 19, West Forty-third-street, with a special clerk on duty between 9 A.M. and 6 P.M. to answer telephone inquiries. On the bulletin board will be posted month by month the regular clinics, medical and surgical, and also laboratory demonstrations, all of which are held at stated hours. Full announcements of daily operations and demonstrations of cases both medical and surgical will, as far as possible, be made on the day preceding their performance. Visiting medical men interested in observing particular operations or the work of particular operators or physicians will thus attain their object with the least trouble. It is hoped that the unexcelled clinical facilities of New York City will thus be made more generally accessible.

The New York Neurological Society.

The following officers have been elected to serve for the year 1913:—President: Dr. Smith Ely Jelliffe. First Vice-President: Dr. E. G. Zabriskie. Second Vice-President: Dr. E. W Scripture. Corresponding Secretary: Dr. J. Ramsey Hunt. Recording Secretary: Dr. C. E. Atwood.

Feb. 1st.

HARVEIAN SOCIETY OF LONDON.—On Thursday, Feb. 20th, at Stafford Rooms, Titchborne-street, Edgware-road, W., there will be a discussion on the Diagnosis of Acute Abdominal Conditions in Children, opened by Mr. E. M. Corner and Dr. E. Cautley, and continued by Sir James Goodhart, Mr. V. Warren Low, Dr. G. F. Still, and others.

THE ASSOCIATION OF CERTIFIED DISPENSERS.—The annual meeting of this association was held in the Court Room of the Apothecaries' Hall, Blackfriars, E.C., on Feb. 6th, Mr. Montagu G. Smith, of the Lewisham Infirmary, presiding. The balance-sheet and annual report showed satisfactory progress, but Mr. A. Howell, who presented the report, stated that the proposed Bill on behalf of dispensers still waited a suitable opportunity to be put before Parliament. Mr. Howell then gave in his resignation of the post of honorary secretary, which was accepted with regret, and on behalf of the members was presented with a gold watch by the chairman, who in a reminiscent speech alluded to the success of the association [illegible] Mr. A. Mowbray [illegible] poke to the same [illegible] elected. Mr. Montagu Smith and Mr. A. [illegible] n were unanimously re-elected chairman and treasurer respectively. Mr. F. E. Trayner, of Hackney Infirmary, Homerton, N.E., was appointed honorary secretary, to whom all communications should be addressed at 13, Carlton-road, Manor Park, E.

Obituary.

HENRY EALES, M.R.C.S. ENG.,

SENIOR SURGEON TO THE BIRMINGHAM AND MIDLAND EYE HOSPITAL.

WE regret to learn the death of Mr. Henry Eales, which occurred after a short illness on Feb. 8th at 3, Queen's Court, Hagley-road, Edgbaston. The son of the vicar of Yealmpton in Devonshire, Henry Eales was born at Newton Abbot in 1852, and began his medical career, as was customary in those days, by being apprenticed to the village doctor. During his apprenticeship there was a local epidemic of scarlet fever, and having to examine the urine of many patients for albuminuria, out of curiosity he examined his own and found that it contained a large amount of albumin. As he had not had fever it is probable that it was merely the albuminuria of adolescence, but little was known on this subject at that time, and so serious was the view taken of his condition that for about a year he was not allowed to continue his medical work. But later, as his general health remained good, he was permitted to proceed with his career, and entered as a student at University College, London, where he gained two silver medals in anatomy and one in materia medica. He took the Membership of the Royal College of Surgeons of England in 1873, and went to Birmingham as house surgeon to the Birmingham and Midland Eye Hospital. At the termination of this appointment he became demonstrator of anatomy and medical tutor at Queen's College, but a vacancy occurring on the staff of the Eye Hospital in 1878 he was elected one of its honorary surgeons. He served the charity, therefore, for 35 years, for several of which he was senior surgeon, while he was also ophthalmic surgeon to the Guest Hospital, Dudley, to the Hammerwich Hospital, Cannock, to the Balsall Heath Dispensary, to the Edgbaston Royal Deaf and Dumb Institution, and medical referee for ophthalmic cases under the Workmen's Compensation Act. At the annual meeting of the British Medical Association in Birmingham in 1911 he presided over the Section of Ophthalmology. He held office as vice-president of the Ophthalmological Society, as chairman of the Pathological Section of the Birmingham branch of the British Medical Association, as president of the Midland Medical Society, and treasurer of the Birmingham and Midland Counties Ophthalmological Society. He delivered the Middlemore lecture for 1897. At one time he contributed a good many papers to the medical journals, including a Report on the State of the Retina in a Hundred Cases of Granular Kidney (*Birmingham Medical Review*, 1880), Uni-Ocular Retinitis Albuminurica, and Toxic Amblyopia (Transactions of the Ophthalmological Society). He was particularly skilful in the use of the ophthalmoscope, his opinion of the appearances being of the utmost value to those who sought his advice in doubtful cases. As a result of wide knowledge and technical skill he built up a large consulting practice, and his death will come as a painful surprise to a wide circle of practitioners and patients who relied upon his counsels.

The albuminuria which had shown itself during his apprenticeship entirely disappeared by the time he went to Birmingham, but he suffered at one time severely from migraine, which became less frequent during recent years. Last Christmas most of his family were ill with influenza, but he appeared to escape; soon afterwards, however, he developed a slight attack of phlebitis in the calf of the left leg. This seemed to get better, but the pain and swelling returned in about ten days, so that he was obliged to stay in bed. On Feb. 5th he had an attack of vomiting with syncope, and this was followed by a rise of evening temperature. These symptoms were gradually improving, and on the morning of the day he died he looked and expressed himself as feeling decidedly better; but a few hours later he died in another attack of syncope. He leaves a widow, two sons, and two daughters; the elder son is senior curate at Kenilworth, while the younger is the resident surgical officer at the Eye Hospital.

Henry Eales was a man of singularly amiable character, and his death makes a gap which to his older colleagues can never be filled. They were sincerely attached to him for his unfailing kindness of disposition, his high character, and thorough loyalty and devotion to his work.

LEONARD NOON, M.B., B.C. CANTAB., F.R.C.S. ENG.

WE regret to record the death of this brilliant young medical man, which occurred, at the age of 35, on Jan. 20th, after two years of illness. Leonard Noon was educated at Charterhouse and Trinity College, Cambridge, studying medicine at that University, at St. Bartholomew's Hospital, and at the Pasteur Institute, Paris. In succession he was the John Lucas Walker student at Cambridge, house surgeon at St. Bartholomew's Hospital, research student in bacteriology at the Lister Institute, and assistant and research worker at the Inoculation Department of St. Mary's Hospital.

After leaving St. Bartholomew's Hospital Noon was engaged almost exclusively in investigating questions of immunity, his work being of a general theoretical nature rather than leading to a direct practical application. This work included investigations into the nature of the toxins and antitoxins of tetanus, the mechanism and localisation of the production of antibodies, the significance and reliability of serum reactions, and similar researches, papers on these subjects appearing in THE LANCET, in the *Journal of Pathology and Bacteriology*, and in the *Journal of Hygiene*. A research which he developed to a practical application was an offshoot from such work as this—namely, the active immunisation against hay fever by means of inoculating extracts of pollen. A paper describing the prophylactic and therapeutic application of this work appeared in THE LANCET on June 10th, 1911, and experience since then has undoubtedly demonstrated the accuracy of his work and its promise for good in the treatment for hay fever.

In private life his interest in volunteering and rifle-shooting dated from his presence for two successive years in the winning public schools team at Bisley for the Ashburton Shield, and this interest he maintained through life. In addition to this, mountain climbing fascinated him, as it often does the strongly intellectual mind. He had not an enemy in the world, and the turn of mind which made him both a wit and an investigator gave him a host of friends and an interest in almost any subject. In fact, Noon was one of those few who really are designed by nature for research work. He had a mind extraordinarily fertile in bold generalisations and new conceptions, and yet he was very ready and ingenious in destructive criticism. He was not, perhaps, very well known to the general profession, for he regarded private practice as interesting indeed on its personal side, but rather an interruption to research; but, as those who were connected with him in laboratory work well know, his early death has deprived English medicine of a powerful brain and of valuable help in the future.

JOSEPH BAYLEY, M.R.C.S. ENG., L.S.A.,

MEDICAL SUPERINTENDENT OF ST. ANDREW'S HOSPITAL, NORTHAMPTON.

Mr. Joseph Bayley, for many years medical superintendent of St. Andrew's Hospital for Mental Diseases, Northampton, whose death at Bryn-y-Neuadd, Llanfairfechan, after 11 weeks' illness we announced in our issue of Jan. 25th, was one of the most highly respected residents of Northampton, a man of conspicuous ability in his profession, and an exceptionally successful organiser. His life work was bound up with the institution with which he was so honourably associated for 48 years.

He was born in January, 1836, and was the son of Dr. Joseph Bayley, of Odiham, Hampshire. He was educated at Reading School, and proceeded to King's College, London, where he completed his education and duly qualified. He entered the Royal Navy as a surgeon, and on the outbreak of the Crimean war served with the Baltic Fleet on board H.M.S. *Colossus*, one of the first-class line of battleships, and was present at the bombardment of Bomarsund and at Kronstadt. For his services he received the Baltic medal. At the conclusion of hostilities he was appointed surgeon on H.M.S. *Shannon*, a vessel of the frigate order. He did not continue long in the navy, but resigned his commission to enter the lunacy service, in which he remained until the end, and to which he made important contributions of a reformative character.

Mr. Bayley's first appointment in his new sphere was that of assistant medical officer at Leicester County Asylum. He afterwards became assistant medical officer at the Salop and Montgomery Asylum, Shrewsbury, under Dr. Oliver, whose daughter he married. On the death of Dr. Oliver he was appointed superintendent of the Shrewsbury Asylum, and in 1865 he was appointed medical superintendent at St Andrew's Hospital, Northampton Here for nearly 50 years he devoted himself to the welfare of the institution, which under his skilful administration became one of the leading asylums of its kind in the country. In the management of the hospital itself, no less than in the treatment of patients, he was most successful, and St Andrew's became recognised as one of the largest and best places for the treatment of patients of the upper and middle classes When he went to Northampton an average of 20 private patients were admitted during the year, nearly 100 are now admitted, and the total number of inmates is about 450 In 1865 the asylum possessed about 100 acres of land, it now owns, including the Welsh estates, over 1000 acres, while the buildings have been repeatedly enlarged and remodelled, so that the hospital now possesses hardly a feature in common with the institution of half a century ago In the care of the patients Mr Bayley always laid special emphasis on the importance of pleasant surroundings and recreations, and his interests, apart from athletics and sport, were mostly confined to the development of the hospital and its estate His work proves him to have been a shrewd, capable, far-seeing man, of large organising power and practical enterprise Clear of perception and of ready decision, he may have seemed sometimes a little quick-tempered, but at heart he was kind and considerate

An old friend and professional colleague writes "Now that his lamented death has terminated a long and much valued friendship, I cannot refrain from giving expression to the feelings of admiration which I have always entertained for his attainments as a physician and his skill in that branch of the profession which he had adopted and for so long practised In the ranks of the alienists Mr Bayley's death creates a loss which it will be difficult to fill, for it was to the position he occupied and which was so widely recognised that the success of St Andrew's as a hospital for the care and treatment of the mentally afflicted was due St Andrew's before his time was a struggling institution with scarcely any but local connexion Patients from all parts of the kingdom, of all degrees, are now sent—a tribute, indeed, to the skill of the superintendent and to the widespread nature of his reputation It has happily been Mr Bayley's lot to complete the work to which he had devoted his lifetime "

DEATHS OF EMINENT FOREIGN MEDICAL MEN —The deaths of the following eminent foreign medical men are announced —Dr Reyter, a Belgian military surgeon, who after serving for some years in the Congo, was appointed physician to the King of Siam, Chulalong-Korn, and continued to act in [illegible] is ennobled with [illegible] " which is unders[illegible] — Kristian Thue, formerly senior medical officer of the Christiania communal infirmaries and of the deaconesses' home In early professional life he had been assistant in the Pathological Institute —Dr A Viaud Grandmarais, formerly professor of medical pathology in the medical school of Nantes —Dr Paulin-Méry, formerly a deputy for Paris —Dr W Mitlacher, extraordinary professor of pharmacology in Vienna —Dr. Philipp Steffan, formerly eminent [illegible] h retired for some years His [illegible] *privat docent* of neurology in the [illegible] A Panella, *privat docent* of physiology in the University of Pisa

---

ROYAL UNITED HOSPITAL, BATH —The annual meeting of the subscribers to the Royal United Hospital was held on Jan 29th under the presidency of the mayor The medical report was satisfactory, and the financial statement showed a deficiency of £1982 at the close of 1912 The proceeds of the special fund raised by Mr A S Wills, to which the late Mr Overton Wills contributed £500, have been used for carrying out several improvements in the hospital, including the installation of an electric lift The chairman referred to the small contributions received from churches and chapels, and suggested the adoption of the custom, observed in Bristol, of having a special Hospital Sunday.

THE NATIONAL INSURANCE ACT.

THE WORKING OF THE ACT

ALTHOUGH it is still too soon to give any definite opinion upon the working of the National Insurance Act, the numerous questions which have been raised in the House of Commons and reported in our Parliamentary Intelligence indicate that difficulties of every kind are being experienced by many of those engaged in administering or providing medical benefit After making due allowance for the political motive behind some of the questions asked in Parliament, the feeling remains that the Government's answers have been at least as ingenious as satisfactory The replies given by Ministers or their responsible supporters have so far thrown little light upon the practical problems of medical benefit, although it is obvious that great efforts are being made to provide the insured with a satisfactory medical service of the kind which the Government desires The official suggestion, however, is that everything is already going on smoothly and satisfactorily, or in the alternative, that all would be well if it were not for the unreasonable opposition of a section of the medical profession The matter can scarcely be left at that, the position is too serious So far as information is at present available, the medical machinery of the Act seems to be working adequately in some districts, but there are undoubted grounds for the irritation which is felt by so many practitioners This irritation, although widespread, is due to different causes in different localities, and it is the duty of those responsible for the administration of the Act to group the various causes together and prescribe remedies which can be applied on a large scale The present impression is that the Act cannot escape amendment, but the exact lines which such alteration should follow have yet to be defined

THE LONDON INSURANCE COMMITTEE

We have received the following election address from Mr E B Turner and Mr Evan Jones —

"Having been requested by a large number of practitioners to stand for election as representatives of the medical profession on the London Insurance Committee we have consented to do so, and ask for your votes and support for the following reasons We hold (1) that the two practitioners elected by the profession to serve on the Insurance Committee for the London area should be entirely independent of the control of that committee, (2) that the interests of the very large number of men who have declined to serve under the Insurance Act and Regulations should be safeguarded as far as possible on that committee by the directly elected representatives The six other medical men nominated and appointed by the Commissioners and the County Council respectively will amply suffice to voice the wishes of those gentlemen who are now serving on the panels, but it is extremely unlikely that they will give any very active support to those who have declined to work under the Act If elected we shall consider that we represent the whole of the profession in London, and shall do our utmost to further the interests of every member of that profession whether he be working under the Insurance Act or not

(Signed) EVAN JONES
E B TURNER"

THE CASE OF THE DEPENDENTS

An interesting situation has arisen in Monmouthshire between the Eastern Valleys Medical Association and the workmen in the district with regard to the terms upon which medical attendance should be rendered to the families and dependents of insured persons Previous to [illegible] this district had [illegible] received 3*d* in [illegible] n return for that [illegible] the arrival [illegible] under the [illegible] go The [illegible] to attend [illegible] There had been originally a suggestion that the sum should be 2½*d*, inasmuch as it was, and is, expected that in some directions there may be an increase of work for the medical practitioners as well as a slight diminution of returns. Now, however, the medical practitioners have agreed upon the smaller sum. But recently they have been asked to meet the Monmouthshire Insurance Medical Committee, which, despite its title, is a lay body, being a subcommittee of the Monmouthshire Insurance Committee for the purpose of medical organisation, when the following terms were submitted to them:—

1. That each person agree to pay 2*d.* in the £ of all wages earned.
2. That such person be allowed a free choice of doctor.
3. For the above payments the doctor to provide medical attendance, including drugs, &c., as has been the custom hitherto, also medical certificates.
4. The medical attendance to include abortions and midwifery.
5. That the doctors agree for the money deducted from the wages of the workmen to be transferred to a committee to be appointed at each colliery, works, or factory.
6. That these terms and conditions be operative until June 30th.

Now to Clause 4 the medical profession forming the Eastern Valleys Medical Association object strongly, while they refuse to be impressed by the fact that in other districts certain practitioners have consented to the principle of free midwifery, as it is known that this concession was only granted under a misapprehension. We understand that temporarily the medical men will give their service in obstetric cases where required, but after June 30th they intend to charge an extra fee of 10*s.* 6*d.* for abortions and midwifery, though they will continue to attend, as before, emergency cases of midwifery gratuitously.

To Clause 5 also the medical men object strongly, and the principle that they stand for—viz., that the money which they have already earned should continue to come straight from the works and not through the hands of any committee—seems to us unassailable by logic. The money has already been earned by the medical men at the time when the wages are due. Why should it not be paid straight to them if they so desire it? Why should it be lodged first with any committee of the workmen? The workmen can only desire to obtain control over the money which the medical profession has already earned so as to obtain some kind of undue influence. No safeguard against medical aggression can possibly be necessary, as the community has complete freedom of choice of doctor; and in no event can it be a respectable proceeding to retain money which has been earned in order to secure power over those who have earned it. We cordially recommend the Eastern Valleys Medical Association to maintain their point.

We may add that the matter has nothing to do with the National Insurance Act in its present form, although it is convenient to refer to it under this heading. The position of the Monmouthshire Insurance Medical Committee in the matter is a little difficult to understand; the question is one to be settled by the workmen and the medical profession, and has to do with services to be rendered outside of the scope of the Act.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Wossidlo, an eminent urologist; Dr. Theodor Landau, a sanitary councillor of gynæcological eminence; and Dr. Otto Kalischer, whose researches on anatomical and physiological questions have long been recognised as valuable contributions to our knowledge, have been granted the title of Professor.—*Bonn:* The dissertation for the M.D. degree may now be presented in German.—*Carlsruhe:* Dr. v. Beck, chief surgeon to the municipal hospital, has been granted the title of Professor.—*Catania:* Dr. Ignazio Beltiore, of Naples, has been recognised as *privat-docent* of Clinical Chemistry.—*Leipsic:* Dr. K. Sudhoff, extraordinary professor of the history of medicine, has been promoted to Honorary Ordinary Professor.—*Montpellier:* Dr. Grasset, professor of clinical medicine, has been appointed to the chair of General Pathology and Therapeutics, in succession to Dr. Rauzier, who has taken Dr. Grasset's chair.—*Munich:* Dr. Georg Mayer, *docent* of hygiene in the military medical school, has been promoted to Professor.—*Wiesbaden:* Dr. Nikolaus Gierlich has been granted the title of Professor.—*Würzburg:* Dr. Martin Benno Schmidt, of Marburg, has been offered the chair of Pathological Anatomy in succession to Dr. Kretz, who is retiring. Dr. J. Riedinger has been recognised as *privat-docent* of Orthopædic Surgery and Mechanical Therapeutics.

THE ALBERT MEDAL FOR A WILTSHIRE NURSE.—The King has awarded the Albert Medal of the Second Class to Miss Elizabeth Holley, of Kingsdown House, Box, in recognition of her gallantry in endeavouring, at great risk to her own life, to save the life of a patient who suffered from suicidal tendencies, and who, while under the charge of Miss Holley, was killed by a train at Box station in November last.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY: THE ANNUAL DINNER.—The annual dinner of the West London Medico-Chirurgical Society was held on Feb. 6th, at the Hotel Great Central, Dr. G. P. Shuter, the President, being in the chair. Mr. Richard Lake, in proposing the toast of "The Imperial Forces," spoke in favour of universal military service, which our more democratic colonies, Australia and even South Africa, had adopted. He commented on the inconsistency of the Socialist Party, which vehemently opposed it, whereas military service, like every other public service, ought logically to form part of their programme. Sir W. Launcelot Gubbins, Director-General A.M.S., in responding, gave a historical retrospect of the political events of 1813. Coming to present times, he praised the newly organised colonial forces for Imperial defence. As evidence of naval progress, he pointed to the new battleships provided by New Zealand and the Federated Malay States, and to the £7,000,000 for naval purposes recently voted by the Canadian Government. The medical branch of the army, he said, was now getting on very well—so well, indeed, that when posts were vacant under the Foreign Office or the Colonial Office, it had become usual to apply to the Royal Army Medical Corps for men to fill them. Army medical officers were acting as governors of provinces; they had been lent for administrative posts to the Red Cross in the Balkan States during the present war, and a bacteriologist had even been sent to Turkey, where he had had a very hard job. Of the Balkan Medical Services, the Servian was the best. He had nothing but good to say of the medical service of the Territorial Forces. If the rest of the Territorial Force were in as satisfactory a condition as its medical service there would be little to complain of. He also eulogised the organisation of the St. John Ambulance Association, which had been a revelation at the review in London last year, and was really a most valuable asset. The President, in proposing the toast of "The West London Medico-Chirurgical Society," said the membership was at present well maintained, as they had over 580 members, of whom 33 were original members. The attendance at meetings during the past year averaged 44, and at the Cavendish lectures never less than 100. He prophesied a distinguished gathering for Sir Berkeley Moynihan's lecture next June, and paid a tribute to the society's losses by the deaths of Lord Lister, Sir Henry Butlin, and Mr. Leonard Bidwell. But he expressed his belief that the society would be adversely affected by the Insurance Act. The profession would be split, as it had been in Germany, according to a conversation he had had with a well-known sociological authority, into two classes of practitioners—insurance doctors and independent doctors, the latter few but respected, consulted and looked up to, the former numerous, but having no standing. In Germany the insurance doctor now ranked below the village parson and the village grocer. The Act was already beginning to affect medical education adversely. The entries at the medical schools had enormously diminished, and unless steps were taken to raise the status of the profession the Government would have either to lower the educational standard or to subsidise the students; in either event the result would be an inferior class of men in the profession, who would have no use for such a society as the West London Medico-Chirurgical Society. Dr. S. D. Clippingdale, in replying, gave some reminiscences of the society, and stated that its financial condition was good. Dr. F. S. Palmer proposed the toast of "The Kindred Societies and Guests," and Sir Francis Champneys, President of the Royal Society of Medicine, replied. Mr. W. McAdam Eccles proposed the health of the chairman, who briefly responded. The entertainment, which consisted of Punch and Judy up to date by Mr. Carl

Harmon and some drawing-room magic by Mr. Herbert Collings, whose patter was humorously apt for the occasion, *was very greatly enjoyed.*

THE BRISTOL MEDICAL CHARITIES.—During 1912 the employees of Messrs. J. S. Fry and Sons collected £590 for the Bristol medical charities.

A CORNISH CENTENARIAN.—The Rev. P. Carlyon, of Pennance House, Falmouth, has recently entered upon his 102nd year. The *Guardian* believes that Mr. Carlyon is the oldest clergyman in England.

OCKENDEN (TORQUAY) CONVALESCENT HOME.—During 1912 the patients admitted to this home numbered 204, and the average number of occupied beds was 19·8. At the close of the year a favourable balance of £42 remained.

UNIVERSITY OF BIRMINGHAM.—Mr. Gilbert Barling, surgeon to the Birmingham General Hospital, professor of surgery in the University, and formerly Dean of the Faculty of Medicine, has been elected Vice-Chancellor.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, LONDON.—The secretary informs us that outpatients' days are now Monday, Tuesday, *Thursday*, and Friday. The change is that Thursday has taken the place of Wednesday, and this was made at the beginning of the year, but a number of new cases still go to the hospital (often from country places) on Wednesdays.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The next quarterly meeting of this association will, by the courtesy of Dr. Rotherham, be held at the Darenth Industrial Colony, Dartford, Kent, on Thursday, Feb. 20th, under the presidency of Dr. J. G. Soutar. Trains leave Charing Cross at 9.55 A.M., or Cannon-street at 9.42 A.M., for Dartford. The following papers will be read after luncheon: Assistant Medical Officers in Asylums, by Dr. J. Beveridge Spence; and A Brief Account of Darenth and its System of Industrial Training, by Dr. A. O. Spensley. *Members will subsequently dine together* at 6.45 P.M. for 7 o'clock, at the Café Monico, London, when morning dress will be worn.

WEST SUSSEX COUNTY COUNCIL: MEDICAL AND SANITARY DUTIES.—At the West Sussex county council meeting at Chichester on Feb. 7th the resignation of the county medical officer of health, Dr. A. G. R. Cameron, was accepted, to take effect from June 30th next. It was stated at the request of Dr. Cameron that the Insurance Act having come into operation since his appointment, and as he had not, he felt, received the support of the committee in carrying out the schemes he suggested, it would be better for him to resign his office. The council resolved that a conference should be held between the various medical and sanitary authorities as to the effective and economical methods of carrying out the medical and sanitary duties in the county, avoiding any overlapping. The position at present is that the West Sussex county council has a medical officer, two assistants, and two school medical officers under a chief, and a tuberculosis officer must be appointed. The conference is to be called together at an early date.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Insurance Act in Operation.

ON Friday, Feb. 7th, the House of Commons had an opportunity of discussing in Committee of Supply various topics which have arisen in connexion with the administration of the Insurance Act. The debate took place on a vote of £1,825,000 for the expenses of the National Insurance Commission. The larger proportion of this money, as explained in THE LANCET of last week, is required to bring the payments of medical men who have accepted service on the panels up to the amount promised by the Chancellor of the Exchequer last year. Naturally the most interesting speech was that in which Mr. LLOYD GEORGE dealt with points of criticism, as he was speaking as the Minister who was primarily responsible to Parliament for the financial arrangements. But the speeches of Mr. WORTHINGTON EVANS, Dr. ADDISON, Sir PHILIP MAGNUS, and Mr. H. W. FORSTER, who spoke from other standpoints, gave expression to views which will be read with interest by medical men. At times a keen controversial element was introduced into the debate.

A point which concerned Parliamentary financial procedure at first occupied the attention of the House. Some Members protested against the proposal to extend the grant into the next financial year, as this was a departure from the practice to grant Supply only for the current services of the year. Mr. CASSEL urged that the arrangements with medical men were provisional for the first three months of the year. In voting money which would be expended in the new financial year which began in April the House would not retain control over the new arrangements Mr. MASTERMAN, the secretary to the Treasury, insisted that the Act contemplated placing the money for the full medical benefit for a year at the disposal of the Insurance Committees in order that they might make contracts with medical men for a year. The House accepted the view of the Government.

The Free Choice of Doctors.

Mr. WORTHINGTON EVANS, who has taken a leading part amongst the members of the Opposition in regard to the Insurance Act, was the first speaker who criticised the administration of the statute. He contended that the "free choice of doctors" had been interfered with by the authorities responsible for carrying out the Act, and that private arrangements for medical treatment had been denied to insured persons. He took exception to the "threats" to send medical men to districts where the local practitioners declined to form a panel, and impose them on insured persons. Such threats, he said, had poisoned the whole administration of the Act, and had affected the administration of every Insurance Committee. He maintained that if a panel was once formed in a district upon which medical men were serving the Insurance Commissioners could not close it so as to prevent other practitioners joining it

Mr. MASTERMAN intervened to say that if the list was adequate to the needs of the neighbourhood it was acted on. If it was inadequate the Commissioners might declare it inadequate and might bring in any other system which they pleased, including what was called the "closed panel system."

The Agitation in London.

Dr. ADDISON, in the course of a long speech, declared that the whole intent and purpose of the medical agitation in London was to break down the Insurance Act Those concerned in it wanted to persuade the insured persons to make their own arrangements without explaining to them what was the project in which they would be involved. He criticised at length the form supplied by the London Medical [illegible] against them He condemned attempts that had been made to prevent medical men coming on the panel.

Sir PHILIP MAGNUS said that the House should remember that the Member for Hoxton (Dr ADDISON), although he was a medical man, did not speak in the name of the medical profession, which would repudiate much that he had said. He also complained that every possible difficulty had been placed in the way of insured persons making *their own arrangements* for medical treatment, and that medical men had been overworked under the Act.

The Chancellor of [illegible]

[illegible]

and suburbs and amongst industrial populations earning good salaries there was a doctor for 500 or 1000 of the population. In Bradford he thought there was a medical man for every 1200 or 1300 people. But in the East-end there was only one doctor for every 4000 or 5000 of the population. One result of the Insurance Act was that well qualified medical men were beginning to drift to these districts for the first time. It was true that many of them were young men who saw an opening, but why did those men not start in these districts before? It was because they could not make a living unless they adopted a type of practice where they had thousands of patients with a threepenny fee and a bottle of medicine thrown in. Now the well to-do artisan and the man who was only earning 10*s.* or 15*s.* a week were both getting the same payment from the Insurance Fund for their doctor. What was the result? The medical man in future, although [illegible] would find that from the [illegible]

beginning to find that out. The system had only been in operation for three weeks, and an honourable gentleman had complained that things were not in perfect order. No proof had been given by him of that. It depended upon a sort of gassy invective that had appeared in just one or two newspapers, but not in all. Who was responsible? Up to Dec. 21st the doctors did not come in under the Act. On that date, within about a fortnight or three weeks of the Act coming into operation for medical benefits, they [illegible] scheme, but a scheme which they them[illegible]efore, and as to which they demanded [illegible] Commons should make a statutory provision to prevent it ever coming into operation. Why should the

Government be blamed for that? This wild-cat scheme had been projected at the instance of one or two men who had led the profession very badly. He thought that all the doctors of the country admitted that quite freely now. That was the real reason why, if there was the slightest confusion, it existed. It was because the doctors refused up to the last moment to accept the terms offered, and put forward terms which they unanimously had rejected 18 months before, and as to which they wished the Government to provide a statutory bar against their ever coming into operation.

The Question of Over-work.

Now as to the question of over-work. There was no proof of that. The only proof that had been put forward was the mention of a certain doctor who had got thousands of patients who insisted on going to him, and they would insist for some time on going to him. It was impossible to prevent them. The honourable Member for London University gave the case of a doctor who dropped dead in the street and there was an inquest and evidence that it was all due to overwork. The whole number of persons—not patients—on his list was 137. The cards had come in since his death, and therefore the Insurance Commissioners knew the facts. Four or five days before his death they were 96 and at the time of his death they were 137. He learned that in London there were nearly 1200 doctors already on the panels, and the number of insured persons was 1,300,000. That meant there was on an average one medical man to every 1100 insured persons. Did those who said that that was extravagant know that there were industrial districts where one medical man would give attendance to 5000 persons? One doctor attended between 3000 and 4000 persons, men, women, and children, in districts like those in South Wales, Durham, and Northumberland. He did not say that at once they would succeed in establishing a perfect system. That was an unreasonable demand. The Opposition were asking the Government to establish in three weeks a system which must necessarily take years to perfect. The Government could say that they had made, not only a beginning, but an extraordinarily successful beginning—a beginning which honourable Members opposite never dreamed of.

Medical Representation on Insurance Committees.

Whose fault was it that the medical profession were not on the Insurance and Advisory Committees? The Insurance Commissioners had asked the British Medical Association to supply a list of doctors in each district to represent the medical profession on the Advisory Committees and Insurance Committees. They refused. And now complaint was made that they were not on the Advisory Committees, and that some regulations were not ready for the purpose of their election. Whose fault was it that the medical profession did not have a share in framing those regulations? Representatives of the medical profession were put on the Advisory Committees. The representatives of the British Medical Association cleared out and withdrew every other man whom they possibly could. What right had honourable Members to complain that these matters were not settled by doctors when the British Medical Association did everything in its power to withdraw every medical man who was invited there to help in framing the rules?

Private Arrangements of Insured Persons.

Regarding what he had promised about the right of insured persons to make their own arrangements, he stood to every word he had said. He had said that it would be possible in any district if insured persons did not care for the capitation system to pool the whole of their money and to draw upon that amount to the extent as far as it went. He went beyond that and said that the insured person would be liable for the balance. What happened in those cases? By this grant the balance had been wiped out and the Government were now enabling the doctors and societies where the insured persons preferred the pooling arrangement to enter into it on the one condition that this grant was to be paid and not a penny piece was to be charged in respect of the balance against the insured persons. In Manchester the very arrangement which he suggested in the Opera House had been carried out and throughout the whole of the great county of Lancashire. What was the arrangement? The medical men there said, "We do not like the capitation system and we do not like treating people at 8*s.* 6*d.* per head, or whatever it may be, and we prefer that the 8*s.* 6*d.*, or 6*s.* 6*d.*, or 7*s.* should be put in a pool and that each of us should attend on the old system our patients and at the end of a given period we should send in our bills, and that those bills should go as against the pool, and if it is insufficient we shall have a dividend." If it was more than sufficient in some districts, a very good use of it would be made. He was asked why the Insurance Commissioners did not allow insured persons to make their own arrangements? This was never intended save in exceptional cases. He was said to be forcing the panel system on insured persons. The panel system was the choice of the British Medical Association, which refused to have anything to do with the Approved Societies. It was now said that the panel system was an instrument of torture manufactured by the Chancellor of the Exchequer for the tormenting of an innocent profession. It was not his invention.

Mr. WORTHINGTON EVANS: But you are using it?

Mr. LLOYD GEORGE: Who put it in my hands? I am doing it for their own good and they will realise it by and by. They convinced me that the panel system is the best. It took weeks to do it. They convinced me so thoroughly that I do not see my way to change again. The panel system, he continued, meant that any medical man could go on it. That meant a free choice of doctors. No Act of Parliament really could compel a doctor to attend a man or compel him to go on the panel. All he could do was what the medical profession asked him to do, and that was to leave an open door to them without any qualification beyond those which they had won at their examinations and which they retained. To try to make medical men serve against their will would be bondage and slavery. The Government wanted perfect freedom for the medical profession. There was no difficulty anywhere except in London. Here, he was sorry to say, it was not medical but political. When the London County Council elections were over this particular difficulty would vanish. The movement for "your own arrangements" had been organised entirely and exclusively by a certain section of the medical profession who wanted to break down the Act for political purposes. The Insurance Commissioners could not permit this arrangement on the scale which it was demanded in London, because it would break down the Act. One advantage of the panel system was that it guaranteed medical service to every insured person, but if they allowed persons to make their own arrangements to any very large extent the doctors would pick out the best lives and leave the broken-down lives to the panel doctors. That would mean that it would be impossible to form a panel at all. This would be grossly unfair. The panel system secured also effective control. It could be seen that a doctor who was on the panel did render the services which he had contracted with the Insurance Committee to give, and if he did not do that he could be called to account. A good many doctors would like to get away from that, but was Parliament to pay the same money to the doctor who was prepared to carry out the regulations of the State and to subject himself to a State supervision, and a doctor who did as he pleased and only had his own patients to control him?

The Attainments of Panel Practitioners.

It had been stated that there would be no proper medical benefits under the Act on January 14th, or if there was medical attendance it would be a sort of refuge for the medical profession. The British Medical Association said that 8000 medical men at least must join the panels in order to work the Act. Now 15,000 had joined the panels. With regard to the quality of the medical men, practically throughout Great Britain almost all who had been engaged in industrial practice were on the panels to-day. London might be a possible exception. In all the great cities—Glasgow, Liverpool, Manchester, Bradford, Newcastle, Birmingham, and Sheffield—the vast majority of the doctors who had been engaged in industrial practice were now on the list, and it was very remarkable that although they had been working for three or four weeks under difficulties which would naturally come at the beginning, the number of complaints which had been received up to the present were infinitesimal in the whole of those districts. Of course, those who were administering the Act could not guarantee the quality of every doctor. There were good and bad doctors, and there were mediocre ones. That was the case in every profession. Money did not always buy a good doctor. But there were first-class, competent, and skilled men on the panels, and if there were doctors on the lists who were not competent, at any rate they had been chosen by the insured persons. These the insured persons need not select. The right honourable gentleman briefly reverted to the case of the East-End of London. There were many districts there which were under-doctored, and he had no doubt that in the next few months doctors would drift into those areas. They were beginning to do so. There was a great deal of hard work to do, but this was due largely to the fact that in the past the poor people had not been attended at all. Half, if not two-thirds, of the population of this district had never received medical attendance at all except what they had got as out-patients of the hospitals. For the first time they could call in their own doctor. That undoubtedly increased the work of the doctors.

Filling up the Cards.

There was another class of work which he had no doubt increased the burden of the doctors at the beginning: that was the filling up of the medical benefit cards. It did not take very long, it was true, to fill up a card, but if a practitioner had 500 patients on his list it took some time to fill in his name and address, and very often the name and address of the patient as well.

Mr. WORTHINGTON EVANS: And there is the book.

Mr. LLOYD GEORGE: I agree, and the trouble is threefold to people who are not in the habit of doing this sort of thing. But that is a burden which is passing away. They have only to do it once and there is an end of it. In future they will only have to fill these cards in in respect of new patients.

Sir PHILIP MAGNUS: No, every time.

Mr. LLOYD GEORGE: No, the honourable gentleman is perfectly wrong. They have only got to fill the cards and send them in the first time. They had to send the names of those who accepted them as doctors once to the Insurance Committee. Therefore, all this trouble which had taken place in the last fortnight was passing away, and in the course of the next week or two there would be very much less. He should like to say a few words about the keeping of books and papers by the medical profession. He thought that it was possible to simplify some of the documents that had to be filled up, and the Insurance Commissioners were looking into the matter. It was one of those things where experience would teach how to work the Act. He had always admitted that amendments would undoubtedly be necessary, and had said that experience alone would show what amendments were required. This was one of the amendments in the Regulations which he thought would be made. He thought that there would have to be some simplification to some of these documents.

"The Tubercular Sixpence."

He would like to refer to what was called "the tubercular sixpence" which made the doctors' 6*s*. 6*d* up to 7*s*. There had been complaints, notably from Scotland, that the money had not been paid entirely out of this Treasury grant but out of the sanatorium 1*s*. 3*d*. That sanatorium 1*s*. 3*d*. was used for dispensary treatment, domiciliary treatment, and sanatorium or institutional treatment, and the suggestion was that the whole of the domiciliary treatment should be provided out of this sum and not out of the 1*s*. 3*d*. It was true that even up to the present most of the work which had been done in respect of sanatorium benefit had been dispensary and institutional. The only part he was concerned with now was that wherein the doctor was called upon for the sum of 6*d*. to deal with the patient in his own home. This was criticised from two points of view. The doctor said that he was not paid enough, and the Scottish county councils that he was paid too much. The number of insured persons who came up for sanatorium treatment at first was necessarily small, but the number would increase from week to week. In November, for instance, there were about 5000 applicants for sanatorium treatment. Half of these were treated at the dispensaries and by doctors at their own homes, and half in sanatoria. The figures received for this week showed that 5000 had been sent to institutions, and the number was increasing. But it was the doctor's duty also to look after the patient when he returned from the sanatorium to see how he got on. He said that to show that the 6*d*., although a liberal allowance, did cover a good deal of work which on the face of things was not apparent. As time went on more and more people would be sent to sanatoria. It would have been a great mistake to attempt to build sanatoria all over the country in six months. The authorities must proceed tentatively even in regard to the treatment of consumption. Concluding, the Chancellor of the Exchequer said that in Germany the Insurance Act had not been brought into operation for a couple of years after it passed, and there was something to be said for
[illegible] ved, and the experience
of H.M. Government to
[illegible] ssible moment. In spite
of prejudice and an organised appeal to prevent the medical profession rendering service 14,000,000 persons were now insured, and he was glad in spite of every obstacle that the Government had determined to go on.

Medical Service in the Highlands.

Several Scottish Members raised the question of the Medical Service in the Highlands.

Mr. LLOYD GEORGE, in reply, said that the recent report of Sir JOHN DEWAR's Committee on the Medical Service of the Highlands revealed the existence of a very special case. Taking any other part of the United Kingdom it was found that insured persons were 1 in 3 of the population. There they were 1 in 10 or 1 in 12. Where the need was greatest the fund was smallest. There were very appalling stories of what had happened there in districts where there were neither doctors nor nurses, and where poor women were left without trained aid of any kind in very trying circumstances. Humanity demanded that in the case of those who garrisoned those remote parts and who produced such a fine race which had rendered gallant service to the Empire, the least that the authorities could do was to go out of their way to help them in the trying condition of sickness which befell all of them. Honourable Members for the Highlands might rest assured that the £10,000 in the Estimates was put down as an earnest and guarantee that the Government meant to take the matter of the medical service in hand.

The vote was agreed to after a debate of seven hours' duration.

The Select Committee on Patent Medicines.

The Select Committee of the House of Commons, which for some months has been inquiring into the subject of patent medicines, has finished its work for the session. It has not been able to take all the evidence which it thought desirable should be heard, and accordingly a report has been presented to the House of Commons recommending that it should be reappointed next session.

HOUSE OF COMMONS.

WEDNESDAY, FEB. 5TH.

Migratory Insured Persons.

In reply to Mr. G. LOCKER-LAMPSON Mr. MASTERMAN said: If an insured person moves from the area of one insurance committee to that of another, he can, by giving notice to the second committee, obtain medical attendance, and also such certificates as are required to be furnished in connexion with any claim for sickness benefit from a doctor on the panel in the second area.

Surgical Appliances under the Insurance Act.

clerical work to do that they
people had died because they
or under the National Insur-
proposed to take to alter this
The answer to the first part
second, therefore, does not
arise.

Mr. HUNT: Does the right honourable gentleman deny that people
died because they were unable to get the service of a doctor under

fit.
said. It is proposed to
edical benefit in order to
iest possible date to the
of the amount's

available out of contributions under the National Insurance Act. It is very desirable, regard being had to the provisions of Section 61 of the National Act, and in order that Insurance Committees may be in a position to enter into contracts for the whole year that the whole amount available for medical benefit should be credited to the committees as soon as possible after the commencement of the calendar year as is contemplated by the financial provisions of the Act, and this cannot be done unless the money is issued from the exchequer before the 31st proximo.

Suggested Amendment of National Insurance Act.

Answering Mr. G. Locker-Lampson Mr. Masterman said: If and when experience shows that amendments of any details of the Insurance Act are desirable, legislation embodying such amendments will undoubtedly be introduced. The Commissioners will be glad to receive at any time and from any quarter any suggestions for possible improvement. Criticism up to the present, however, has been singularly barren in constructive suggestions.

THURSDAY, FEB. 6TH.

Sanatorium Benefit in the East End.

Mr. H. Lawson asked the Secretary to the Treasury whether arrangements would be made to prevent consumptive patients in the East End of London from being kept nearly eight weeks before any decision was given as to whether they could obtain sanatorium benefit, seeing that under the present circumstances more harm than good was in many cases done [illegible] nt.—Mr. Masterman replied: I am [illegible] ecision as is suggested by the honour- [illegible] nts have been kept waiting a short [illegible] Patients who remain at home until [illegible] ria, so far from being prevented fro [illegible], are provided with it, medical attendance, medicine, and articles ancillary to their treatment, such as extra food, all being supplied to them at the expense of the insurance funds. I am informed that the Downs School at Carshalton, which is being equipped as a sanatorium for over 300 cases, will commence receiving patients from the London Insurance Committee in a few days' time, and so relieve any waiting list at present existing.

Private Arrangements under the Insurance Act.

In reply to Mr. G. Locker-Lampson Mr. Masterman said: I am not aware of any general refusal of any Insurance Committee to grant permission to insured persons to make their own arrangements when the panel system is working, although I believe some committees have suspended the granting of such permission until they are satisfied that a panel system to provide adequate attendance for all insured persons is assured.

Middlesex Insurance Committee and Panel Contracts.

Answering Mr. Newman Mr. Masterman said: I understand that the Middlesex Insurance Committee recognised that it was impossible to allow doctors who had made contracts for a definite period and had not been released to break these contracts and yet undertake the attendance of insured persons within the same period upon different terms.

Medical Representation on Insurance Committees.

Mr. Newman asked the Secretary to the Treasury whether Regulations would be framed by the Insurance Commission to provide for the election of two representatives of the medical profession on each Insurance Committee; whether he would state why these representatives had not been already elected; and whether, where more than two candidates offer themselves for election, it was proposed that the method of election should be that known as the block vote or that known as the single transferable vote.—Mr. Masterman replied: Regulations have been issued providing for the election of two representatives of the medical profession to each Insurance Committee, and a circular explaining the method of election and enclosing a nomination paper has been sent to every practitioner appearing on the Register. The method of election is that known as the single transferable vote.

Local Medical Committees.

Mr. Hills asked the Secretary to the Treasury whether any Local Medical Committees, as required by the National Insurance Act, had yet been formed in any county, and, if so, how many and by what method such Committees were appointed.—Mr. Masterman answered: Yes; 71 Local Medical Committees have been recognised by the Insurance Commissioners in accordance with Section 62 of the National Insurance Act. The Commissioners require to be satisfied that the Local Medical Committee, before it is recognised, is fully representative of the medical practitioners in the area.

MONDAY, FEB. 10TH.

The Distribution of Insured Persons.

Sir J. D. Rees asked the Secretary to the Treasury to state under what obligation a doctor on a panel lay to accept as a non-paying patient a person who chose him as his or her medical adviser; and what redress had a person who, having chosen a particular doctor, was rejected by such doctor, or perhaps by a succession of doctors chosen by him or her.—Mr. Masterman replied: One of the advantages enjoyed by a doctor who accepts insured persons on his list is that none of them are non-paying patients, and no obligation rests on any doctor on the panel to accept a non-paying patient. The Regulations provide for the distribution among the doctors on the panel of any insured persons who have been refused by the doctor whom they have selected, and so far as is practicable under arrangements made by the doctors on the panel.

The Income Limit in Perth.

Mr. Frederick Whyte asked the Secretary to the Treasury whether he had now received any communications on the subject of the reported decision by the Perth Borough Insurance Committee to fix an income limit for the purposes of medical benefit; whether he was aware that due public intimation of the intention of the Committee was not given to those concerned; and whether he proposed to take any action in the matter.—Mr. Masterman said in reply: I understand that public notice of the proposal to fix an income limit was given by the Insurance Committee by means of advertisement in the public press, and that a public meeting was held on Saturday last at which representatives of Approved Societies as well as medical practitioners discussed the question. The Insurance Committee are further considering the question early in this week.

Medical Referees and the Panel.

Mr. Bird asked the Secretary to the Treasury whether medical referees under the Workmen's Compensation Act were debarred from going on to the panel in accordance with the terms of the memorandum issued to them.—Mr. Masterman replied: The answer to the question is in the negative.

Surgical Dressings under the National Insurance Act.

Mr. Rupert Gwynne asked the Secretary to the Treasury whether there were any regulations or provisions by which medical practitioners under the National Insurance Act could supply surgical dressings and lotions to insured persons in the case of accidents and obtain payment for the same from the Insurance Committees; and, if not, would he [illegible] for such cases.—Mr. Masterman [illegible] the [illegible] being [illegible] circumstances stated.

TUESDAY, FEB. 11TH.

Ireland and Medical Benefit.

In reply to Mr. Fred Hall (Dulwich), Mr. Masterman said: If medical benefit were provided in Ireland upon the same terms as in Great Britain, and if the contributions were adjusted accordingly, the additional cost to the Exchequer over and above the present provision on the basis of those actually insured would be approximately £40,000. The general extension of medical benefit to Ireland could not be effected without legislation.

Sickness Certificates in Ireland

Mr. Masterman informed Mr. O'Donnell that it was stated by the Irish Insurance Commissioners that a certain amount of difficulty had arisen in Ireland in connexion with sickness certificates. A sum of £50,000 was being taken in the supplementary estimates which would be to a large extent available for defraying the reasonable cost of such certificates. Societies could adopt alternative methods of obtaining evidence of illness if excessive fees were charged for medical certificates, and the Irish Commissioners had issued to all societies and branches in Ireland a circular pointing out that the societies, if they thought fit, might obtain evidence of illness by the adoption of a system of lay visitors, by the inspection of medical relief registers, or by the acceptance of a written statement from a clergyman, magistrate, or other responsible person who could testify to the claimant's incapacity for work.

Insurance Committees and Free Choice of Doctor.

Mr. Godfrey Locker-Lampson asked the Secretary to the Treasury whether the Insurance Committees in the county of Middlesex, the Isle of Ely, and Sheffield had refused free choice of doctor outside the panels unless exceptional circumstances were proved, and whether any definition of exceptional circumstances had been laid down by them.—Mr. Masterman replied: I am not aware that the three Insurance Committees mentioned have acted differently from other Committees. The Act only contemplates permission being given to an insured person to make his own arrangements in exceptional circumstances. It is for the Committee to decide upon each application whether the circumstances of the case are, or are not, exceptional.

Unqualified Practice under the National Insurance Act.

Sir J. D. Rees asked the Secretary to the Treasury whether an insured person was entitled to the provision of the services of a herbalist instead of a doctor when desired; and what benefits would be provided for Christian Scientists under the National Insurance Act.—Mr. Masterman said in reply: Duly qualified medical practitioners alone have the right to be included in a panel list. It is, however, open to the persons who belong to an unorthodox school of medicine to apply to their Insurance Committee for permission to make their own arrangements for medical treatment, and if such permission is given the committee will make a contribution towards the cost of treatment.

Operations on Insured Persons.

Mr. Fred Hall (Dulwich) asked the Secretary to the Treasury whether Regulations had been made as to the arrangements to be followed for the performance of operations on insured persons who could not be dealt with at hospitals; and whether these would in all cases have to be dealt with at the patient's own home.—Mr. Masterman answered: No such Regulations have been made; whether an operation should be performed at a patient's home, or at the doctor's surgery, or at a hospital must depend upon the circumstances of each particular case.

The New Vivisection Regulations.

Mr. Fred Hall (Dulwich) asked the Secretary of State for the Home Department to state how it was proposed to appoint the inspectors to carry out the new regulations with regard to vivisection; the salaries to be attached thereto; and whether the positions would be filled by open competition.—Mr. McKenna furnished the following reply: I propose to select from among all candidates who may apply those who appear to me best qualified to discharge the duties of the post. If by open competition the honourable member [illegible] appointment. The appointments will be made for a year in the first instance, and the salary will be £500. If th[illegible] continued the salary will rise by £20 a year to a [illegible] persons appointed will be required to give thei[illegible]

WEDNESDAY, FEB. 12TH.

Limited Panel Contracts.

Sir Philip Magnus asked the Secretary to the Treasury whether, in the case of a doctor having joined a list or panel on the understanding that he contracted to attend only a limited number of insured persons, he might be required later on, as a condition of his remaining on the list or panel, to attend such additional number of insured persons as might be allotted to him as his share of the residue of persons to whom no doctor had been previously assigned.—Mr. Masterman [illegible] doctor attending only a limited number of patients there is no reason why it should be made a condition of his remaining on the panel that he should attend an additional number of insured persons, so long as the arrangements are in force.

Speaking on the Appropriation Bill, Mr. MASTERMAN said that the Insurance Commissioners saw no objection, now that adequate medical attendance was assured to insured persons, to permitting Insurance Committees to make arrangements with the doctors already on the panels for the admission to the panels of doctors who should treat only such persons as desired to continue to be treated by them.

A DIARY OF CONGRESSES

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses It is unnecessary to issue the lists of all these functions week by week and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement The following Congresses Conferences and Exhibitions are announced :—

March 1st (University of London) —Eugenics Education Conference

„ 1th 20th (Paris) —International Congress of Physical Education

(Easter week) (Berlin) —Fourth International Congress for Physiotherapy

of the German Association

Congress of the German Surgical Association

April 3rd 9th (London) —International Congress of Historical Studies

„ 6th-12th —Health Week

„ g Conference

„

May 14th-18th (Paris) —Twenty first Annual Congress of the Royal Institute of Public Health

July 7th 12th (Exeter) —Twenty-eighth Congress of the Royal Sanitary Institute

„ 16th 18th (Oxford Keble College) —Oxford Ophthalmological Congress

Aug 4th and 5th (London Caxton Hall) —English speaking Conference on Infant Mortality

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR" and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention should be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed " To the Sub Editor

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed " To the Manager "*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

THE INDEX TO THE LANCET

THE Index and Title page to Vol II of 1912 were given in THE LANCET of Dec 28th, 1912

VOLUMES AND CASES

VOLUMES for the second half of the year 1912 are now ready Bound in cloth, gilt lettered, price 16*s* , carriage extra

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2*s* , by post 2*s* 3*d*

To be obtained on application to the Manager, accompanied by remittance

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W C , are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c , should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world

The rates of subscriptions post free from THE LANCET Offices, have been reduced and are now as follows —

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs 50 per month)

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C

TO COLONIAL AND FOREIGN SUBSCRIBERS

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied

SOLE AGENTS FOR AMERICA—MESSRS WILLIAM WOOD AND CO , 51, Fifth Avenue, New York U S A

The Hunterian Oration

Delivered before the Royal College of Surgeons of England on Feb 14th, 1913,

BY SIR RICKMAN J GODLEE, BART, M S. LOND., F R C.S ENG, HON. M D. DUB,

PRESIDENT OF THE COLLEGE, ETC

GENTLEMEN,—The picture which on these occasions hangs over the head of the orator was, as is well known, painted under peculiar circumstances John Hunter was urged to sit to Reynolds by his friends, and principally by Sharp the engraver, who, with strange prescience, foresaw that his engraving of the portrait would prove to be his *chef d œuvre* But Hunter objected, he thought *it almost as great a* waste of time as he did only four years later, "when he fairly wished Sir Joshua and his friends at the devil when called on to take part in the funeral of this eminent artist and delightful author" Besides, he would not allow them to pay for it, and he had always more than enough use for his own money At last, however, when he was 60 years old, he yielded *It is easy to imagine him*—and with much sympathy—fuming and fidgeting in that great armchair, with the description of his specimens (on which he set great value, but which was burnt after his death by Sir Everard Home) at his side Time after time the master tried to catch his likeness, but without success, and he was almost giving up in despair, when suddenly on Hunter s face came this rapt expression, as, with his mind fixed on other things he ceased to be worried with his surroundings Quick as thought the canvas was turned upside down, and between the original legs appeared this face which even in the present cracked and faded condition of the picture has been the admiration of succeeding generations We have been blamed for having allowed it to become so ruined, but possibly the way in which it was painted may partly account for the disaster

Look at the picture! I have gazed at it, *in season and* out of season, for half a lifetime trying to guess what was the thought that calmed and possessed his restless mind And now, at last, I seem to know For one thought occurs again and again in all his writings, and speaks to day from his museum to him who grasps the idea of its arrangement *What is Life?* That mystery which baffled the intellect of the ancients and which still, *pace* Professor Schafer, is awaiting solution What is Life? And then I recall his strange formula, which haunts the memory like a sort of wild refrain, "*Body, Blood, and Motion!*" When the motion *of the blood stops the blood dies*, and then the body dies, some parts of it sooner, some later, but it dies, although there is no difference in its constitution perceptible to the senses Truly as he observes, "mere composition of matter does not give life, for the dead body has all the composition it ever had *Life is a property we do not understand, we can only see the necessary leading steps towards it*

We all admire the picture But what would we not give *to see for a moment the failures which still* exist under the paint at the lower part of it? That would be a likeness of the real man such as we can only gather from hearsay

LONDON IN THE TIME OF HUNTER

If he were to slip out of his frame into our midst it would give us a shock to see, instead of that inspired philosopher, a sturdy, thick set man in a brown, eighteenth century full-skirted coat and breeches, a bull neck an underhung jaw, thin white hair that had once been red, and such an eager manner and such a sparkling eye! He could not have stepped into this theatre for the place where our College stands was occupied by residences, except one part in the rear where there was an old theatre giving on Portugal street But I can imagine him crossing the open treeless square, with a pond in the middle and making his way by Queen street and Long Acre or the Strand to his house in *Leicester Fields* He would hardly have ventured on a cross cut through St Giles's, for even in *my* young days it was a questionable district for respectable pedestrians I think of the people he might have met Dr Johnson, blinking as he groped his way towards the Cock Tavern in Fleet-street, Fanny Burney, the novelist, bowing from her sedan chair to Edmund Burke or Wyndham, "Sir Roger in his coach and four, Mrs Siddons or Garrick stepping towards Drury-lane; the refined Percival Pott, his greatest rival, or Warren Hastings with his anxious face *And one might wonder that he is scarcely mentioned in the* writings of Mrs Montagu or Madame Piozzi, and that he does not seem to have mixed much with the distinguished intellectual circle whose names are still to us household words, if one did not think of the enormous amount of work which Hunter crowded into the 45 years after he left Scotland at the age of 20, with no great reputation *for* diligence or application I see the strange dress of the common people, and hear the noisy rumble of the huge waggons, and the "cries of London"—that little London of 500,000 or 600,000 *inhabitants, which in 1740 did not extend* beyond Old street, Queen square, and Portman square on the North, "Tyburn Tree" and Westminster on the West, Mile-End on the East, and was connected by *two bridges only with the small borough of Southwark*, enclosed by the upward loop of the river It was like a great isolated country town, and from this square ten minutes' walk led to green fields and farms and streams and primroses and foot-pads At Leicester-square his great yellow coach, which had crossed the drawbridge at the back of his house leading into Castle street, would be waiting for him, and his coachman would *drive off* with his *two bay stallions to his country* house at Earl's court If Leicester square was at all in the state I first remember it, it must have been a waste indeed *He would go down* Coventry-street, looking much as it does now (though Regent street did not exist), and along Piccadilly, then occupied only by the mansions of the great Passing St George's Hospital he would turn to the left down Bell lane now the Brompton road, through fields with hedges and trees, till he reached his destination at Earl's Court, two miles from London

Pictures of the house show it as a plain stuccoed villa, evidently built in stages, standing in grounds of moderate dimensions It looks uninteresting, but we know that there were caves and dens of the earth, in which wild *beasts were* kept and from which they sometimes escaped, and coppers in which the skeleton of a giant could, if need arose, be *quickly freed of its flesh* Other strange animals roamed about the park, and a stuffed crocodile hung, like a presiding saint, over the front door Within were carried out all sorts of investigations, for it was to Earl's court that he retired whenever he was able—*too* far from London for casual interrupters but not far enough to miss calls *of great importance* or urgent necessity There no doubt many of the preparations were made, if not mounted, which found their way *into the Museum at Leicester* square

HUNTER'S MUSEUM

There is an engraving of No 28 at the south east corner of Leicester square, and we can picture the *front* parlour and the study, and afternoon bedroom, and *the print room* and the sedan chair standing in the hall He bought the lease of this house and of one at the back in Castle street, and *between them he erected a building at a cost of over £3000* On the ground floor were the great parlour for weekly meetings of his medical friends and a theatre for his lectures Above it was the Museum lighted from the top, 52 ft long and 28 ft wide, with a gallery all *round* The house in Castle street was used for the different *branches of human* and comparative anatomy, for his printing press and publishing departments, and contained a sitting room for his *students*

Let us try to think what this Museum was like and why it was formed, for it seems strange for a busy surgeon to devote a large part of his house and a very large part of his life and nearly all his *fortune to the formation of an* enormous anatomical museum One could not *imagine such a collection* now in Harley street or Cavendish square

In the first place, it must be borne in mind that Hunter *was a man of phenomenal industry*, whose mind was interested in everything to do with nature, to him the pursuit of natural history amounted to a passion—a passion that many of us can sympathise with, "for Nature never did betray the heart that loved her" *But it must* also be remembered that he possessed in an almost exaggerated degree *the mania for* collecting, which is also a vice not quite unknown amongst my audience, who sit on Chippendale or Empire chairs, *speculating on the works of the Old Masters* Another vice he had which is shared by too many of our profession He only thought of money as a means for gratifying his ruling passion, and so he crowded his house with works of arts, and his museum, not only with specimens which illustrated his novel views of physiology, but with others interesting only from their rarity or beauty. He thought no more of spending £500 for the skeleton of the Irish giant, or buying a picture by Zuccarelli, or Hogarth's prints, than is now thought of paying a thumping sum for a sixteenth century bronze; and though he took the keenest interest in his patients' diseases, he looked at the "damned guinea" only as the means for enriching his collection; and so it is no wonder that he left little to his heirs besides this incomparable Museum.

But it must not be thought that this was a mere omnium gatherum of everything that came in his way—very far from that. It only needs to examine the specimens now in the Museum, all religiously distinguished by their two black figures, to appreciate that either he never put up anything except the best—which is not likely—or that, like a true collector, he eliminated all except the best; for they are nearly all of superlative excellence, and illustrate in a striking way the particular object for which they have been preserved—that is, the physiological or pathological process, not the mere isolated anatomical fact.

It is almost inconceivable when looking through Hunter's posthumous papers that out of this apparent chaos such a definite plan could emerge as the groundwork of the Museum. One is lost amongst such subjects as the sociability of man and animals, the rising of animals, air in the bowels, the mind, fossils, or parts whose uses are not known. No one can attempt to summarise such a vast variety of material, b catalogues, which from Owen's which the would be re, though in to what follows or rship of some ee had be dread- a man endowed admire without ence, absolute exactitude, limited patience, and at the orseless critic of the absence of ever, after invoking the support of our conserv o curators, who would admirably defend me, I should invite him to walk through our Museum. But first I should tell him that his collection waited in its original abode till 1800, when it was taken over by the College, and that during that time it was carefully watched over, kept clean, and dusted by his trusty assistant Clift.

THE CONSERVATORS OF THE MUSEUM.

Clift, it may be observed, was born in great poverty and was sent up from Devonshire by Hunter's sister, and was engaged by him on Feb. 14th, 1792, a year and a half before his death, without fee, to write and make drawings and dissect and take part in the charge of the museum. Poor faithful Clift! He got 7s. a week for seven years from Matthew Baillie and Home, and kept patiently dusting and cataloguing. At last, when the Government gave £15,000 for the collection, and subsequently £12,500 in addition, and the College gave £21,000 for the building of the first museum, he was made the first conservator. He held this post till 1842, when he retired on account of ill-health, with a pension of £400 a year.

And here I should slip in the piece of information that the College has spent no £500,000 upon its construc- ti tenan time.

ing al other museums, such iz per, Heavyside, Brookes, ff in, and other famous to it himself, ly master— I had almost said he was an abject worshipper—and with the assistance of his son he got it into order for display and development by the more distinguished men who followed him.

The first of these was Richard Owen, a man of a different type, whose very aspect suggested cerebral hypertrophy. He was appointed assistant conservator in 1827, and full conservator in 1842. So he worked long with Clift, married his daughter, and was thoroughly imbued with his father-in-law's hero-worship. He became a comparative anatomist and palæontologist, and added many of those weird forms which now occupy the floor, glyptodons and megatheriums, and the giant elk, and fossils by the gross. But his great work was the publication of the memorable descriptive and illustrated catalogue of the physiological series of comparative anatomy, to which department he made important additions. Owen's was a stressful reign; for he could ill brook control, and the Museum committees were frequent and stormy. And so, great man though he was, he left without a vote of thanks or regret, to take charge of the Natural History Department of the British Museum in Bloomsbury in 1856.

Then came Quekett, of the Quekett Club fame, who had been student dissector at the College and assistant curator since 1842. He was essentially a microscopist, one might say a born microscopist, for his father was one before him, and at the age of 16 he gave lectures on microscopical subjects, illustrated by a microscope he had made for himself out of a roasting jack, a parasol, and a few pieces of iron he had purchased at a neighbouring marine store. He added little to the Museum except a valuable microscopical collection, but he drew up a catalogue of the fossil organic remains of plants. He was, as his portrait indicates, a jovial man. He retired on account of ill-health, and when he died at Pangbourne in 1861 he left a penniless and, alas, unpensioned widow.

And he was followed by Flower, a strong organiser and a born manager of men, whose graceful figure and handsome face many of us can remember. Under his peaceful rule dissensions ceased. He was, to begin with, assistant surgeon at the Middlesex Hospital, and served as surgeon in the Crimean war. He was appointed conservator in 1861 and stayed until 1884, when he succeeded Owen in the charge of Waterhouse's terra-cotta palace at South Kensington. He developed into a pure comparative anatomist and specialised in bones, and especially human bones. He amplified and enlarged Hunter's osteological collection, and has left in it a memorial to his industry and skill to which I shall refer later.

A word of explanation with regard to the natural history collection must here be introduced.

There were no natural history museums in London before Hunter's time. But the British Museum in its earlier days began to make such a collection. In 1809 they wanted to get rid of these specimens and sold them to us for £180, but in 1814 they found they had made a mistake, and so we sold them back again, but by good fortune retained the Evelyn plates of vessels and nerves, made in 1642 by a professor in Padua under Evelyn's direction and given by him to the Royal Society and by them to the British Museum. Dr. Keith has had them properly mounted, and they now have a prominent place allotted to them.

Hunter had a good many stuffed animals, but after obtaining a Royal Warrant, which is required before any of his specimens can be disposed of, they were sold or otherwise got rid of in 1829, 1834, 1843, and 1876; including, alas, those collected by Captain Cook. It must be remembered that at one time we used to fit out exploring expeditions, such as those of Captain Everard Home, Banks, Beechey, Franklin, Ross, Parry, and Darwin, with bottles and apparatus, and have now in our possession many of the specimens which they brought home.

When Flower left in 1884 he was succeeded by the amiable, retiring, laborious Stewart. Being a man of artistic temperament, he was attracted by such subjects as mimicry, symbiosis, and protective colouring. He was at first a teacher of physiology at St. Thomas's Hospital, but after his appointment here worked as a comparative anatomist. He extended Owen's rearrangement of the Physiological Series, which was not quite on Hunter's lines, as they both took rather the mechanical view as opposed to the physiological. A consummate draughtsman and a clear exponent, he made many discoveries which he was too indolent (may I say) to publish, but they remain on the stands as silent but eloquent witnesses of his work.

And now I should tell Mr. Hunter that the mantle has fallen upon a thoroughbred compatriot of his own, and should feel confident that between them there would be illustrated the *action of the principle of universal sympathy*, except, perhaps, that there might be some incongruity between the northern accent of the one and that which used to be current in the neighbourhood of Long Calderwood. It would be necessary to add that under Dr. Keith's guidance, with the able assistance of the curators, Mr. Shattock and Mr. Byrne, we are trying our best to keep Hunter's spirit in view in all the changes which have been lately made and are still in prospect, and that "Body, Blood, and Motion," is our motto, and that to illustrate the processes of life is our leading idea.

These are the conservators, but it would be wrong not to mention some of the illustrious workers who, without holding that office, devoted much time and labour—often a labour of love—to the Museum. Pre-eminent amongst them is Sir James Paget, who examined and elucidated so thoroughly, and wrote so much of the descriptive part of the catalogue; and besides his there are the names of Stanley, of Goodhart, and Doran and Eve, and men like Elliot Smith who have added complete chapters to its story.

GROWTH OF THE MUSEUM.

Some idea of the way in which the Museum has grown may be gathered by remembering that no part of the original building remains. The room which was first erected in 1800 and completed in 1813, just a century ago, partly on the site of houses belonging to the College, partly on that of the old theatre in Portugal-street, occupied a position in the middle of the three existing galleries, and this was large enough to contain all the 13,682 of Hunter's specimens, including some which, as I said, have disappeared, as is shown by a very indifferent sketch, apparently of Clift's, in which the head of a giraffe, no doubt the one which in 1834 went with the other stuffed animals to the British Museum, appears looking out of the Museum through the gallery into the Cabinet room, whatever that may have been.

The Museum is now more than three times the original size, and contains 64,766 mounted specimens; and there are besides still unexplored stores to which constant additions are being made.

Some people may wonder why we try to keep adding to our invested funds. I say nothing about the uncertainty of riches, though that is perhaps more obvious now than when the phrase was coined. But I should like to point out that the Museum will continue to grow, and that we may some day wish to enlarge it, which would involve three things: diminution in income from rents, loss of interest on capital expended, and increase in expenditure for upkeep.

The Museum now consists of three long rooms, two of which are parallel with one another, and the third at right angles to these, both the first and the third being divided into two parts. Roughly speaking, the last contains the Physiological Series, while the two others are devoted to Anatomy and Pathology; but there are other rooms to which reference will be made; and scattered throughout are curiosities which have to find places where they can. Here a huge skeleton of a whale floats, like Mahomet's coffin, in mid air, and elsewhere are such unlikely objects as the clothes of a man stripped off by lightning, leaving him intact, or the initials—perhaps of two lovers—found on splitting a beech tree, healed over and buried beneath many annual rings.

A TOUR OF THE MUSEUM.

But it is really time to proceed with the proposed formidable inspection, and I would suppose that we begin by conducting Hunter through the door opening out of the Conservator's office into the smaller part of the eastern room, in the cases round the walls of which is the commencement of the series of comparative osteology.

He would gaze with astonishment at the group of vast fossil skeletons, and might possibly ask us what they had to do with his Museum—a question which might at first seem hard to answer But the great black statue of Owen in the corner would remind us that in 1855 he gave some lectures in this theatre on Hunter's published and posthumous papers on fossils, and that he showed by many quotations that Hunter began to hold almost modern ideas about geology and [illegible] 17[illegible], when he was serving with the [illegible] of Noah's deluge had not satis[illegible] Fracastoro in the fifteenth century, but it still hampered the thoughts of scientific men of the eighteenth century. It is therefore remarkable that Hunter was able to emancipate himself so completely and, to quote from Owen, to recognise "first, the effects of running water as in valleys and river courses; secondly, the deposition of the matters so transported to the sea, noting the different distances to which such transported matters would be spread over the sea bottom, according to their size and other physical characteristics; thirdly, the erosive action of the sea on coasts, as moved by tides, currents, and winds; fourthly, the power and mode of operation of a retiring sea on a rising land; fifthly, igneous expansive force and volcanic eruptions; and sixthly, deposits through animal or organic agency."

This includes almost every agency of geological dynamics recognised at the present day, except that of ice, and was arrived at "by supposing from the state of the earth as it is now what must have taken place formerly." From this standpoint Hunter seemed to have an inkling of the origin of species and the gradual evolution of life, and was able to contemplate in some measure the antiquity of man. Thus it is fitting that (presided over by Owen) these horrid monsters should guard the portals of our Museum and that Hunter's 2773 fossils should be lodged, with his invertebrate specimens, in a special place of honour.

So we should turn to the left and tell him that the crowd of vertebrate skeletons in the next room, among which he would recognise many of his own favourite preparations, should really be in the cases along the walls, only unfortunately they are too large. These cases contain the continuation of the comparative osteology series. In passing we should [illegible] preparations illustrating th[illegible] mammalian bones. On our wa[illegible] be explained that leading out of them are the new rooms added last year containing a collection of surgical instruments, the embryo of a medico-legal collection, his own invertebrate collection and the fossils to which I have just referred. And then in the galleries he would find his own physiological series amplified and enlarged. We should show them with confidence, tempered by the fear that he might impatiently resent certain modifications of order and arrangement, though he could not fail to recognise that the *idea* had been grasped. We should point out that the physiological series still illustrates processes rather than isolated facts, and is, therefore, drawn from the whole range of comparative anatomy. Thus, taking as an example the heading "Kidney," he would find specimens from 133 animals other than man, no less than 71 out of the total 144 being his own; and that the same thing is carried out under the other headings.

In order to grasp the plan on which the whole Museum is arranged, it would then be best to visit the ground floor of the eastern rooms. Beginning with the cases on the walls, we should find illustrations of normal (and, it must be owned, some abnormal) varieties of humanity, amongst which Byrne, the Irish giant, would be a familiar object. There are skeletons of dwarfs, of average men and women, and of geniuses and of criminals; and then we should start on the splendid collection of skulls illustrating ancient and modern types and examples of those of all the races under the sun, present and extinct. This carries round both sections of the room and a considerable part of the middle room.

The floor of the eastern rooms is devoted to specimens illustrating human anatomy. First, the collection of disarticulated bones in progressive series, showing their development from early fœtal life to maturity; and then dissections, which are said to be unequalled, mostly made by the skilful hands of Mr. Pearson, who has been prosector here for 56 years.

The Pathological Section.

And now there would be left only the pathological section to which it would be my duty and my pleasure to especially invite the attention of my guest, as I now do that of my audience.

Hunter's catalogue of this part of his collection was left in considerable confusion, but it is clear that his idea was to divide it into two main groups, one illustrating processes of general pathology, the other the various morbid processes affecting particular organs. This has long been before the minds of those who have had charge of the Museum. But it is only during the last year that the Council has made arrangements for a full display of specimens illustrating general pathology.

The floor space of the central room has been cleared in a way it is needlees to describe, and if it were only possible to find a better home for the suspended skeleton of the whale, uninterrupted daylight would illuminate groups of glass and gun-metal stands so arranged that they can be observed from all sides, labelled and supplied with handy card catalogues, and following one another group by group in the following order:—

1. Hypertrophy.
2. Aplasia.
3. Hypoplasia.
4. Atrophy.
5. Degeneration.
6. Necrosis.
7. Repair and grafting.
8. Inflammation.
9. Infective diseases—
    Bacterial: Glanders, Acute Endocarditis, Diphtheria, Tubercle, Leprosy, Actinomycosis.
    Protozoal: Syphilis, Tropical Diseases, &c.
10. Cysts.
11. Tumours.
12. Foreign bodies.

I have placed upon the table a few Hunterian specimens in order to show that it has not only been possible, but highly advantageous to use them for this purpose. You will observe what remarkably fine preparations they are.

1. A ringed stem to illustrate	Hypertrophy.
2. An edentulous jaw to illustrate	Atrophy.
3. Atheroma of the aorta „	Degeneration.
4. Experimental necrosis on the metastarsal bone of an ass to illustrate	Necrosis.
5. A hare-lip cured } to illustrate ...	Repair.
6. A fractured clavicle }	
7. A cock's spur implanted in the comb to illustrate	Grafting.
8. Myositis ossificans ... . } to illustrate	Inflammation.
9. Necrosis of skull following a scalp wound ... ... }	
10. Tubercle in the lung of an ox } to illustrate	Infective diseases.
11. Specific necrosis of the skull }	
12 Gas cysts in a hog's gut to illustrate ...	Cysts.
13. Secondary sarcoma of rib „	Tumours.
14. Gunshot injury of humerus of swan to illustrate	Foreign bodies.

It would have been impossible in Hunter's time to make so complete a list as this because the great group of infective diseases would have been simple and unanalysed. If he had possessed a knowledge of bacteriology it would have saved him a vast amount of fruitless speculation, or at all events speculation which now seems to be disappointingly beside the mark. I think he would have lingered long over this department, for I hope it has been made clear that what has just been said is intended to be the kernel of my address: that this exhibition of illustrations of general pathology though a new departure, is Hunter's idea. and that it is not only new but good and, as far as I know, unique. I would, therefore, urge my hearers to visit and study it and judge for themselves of its utility and interest and of the skill of those who have brought it together.

The tour of the Museum would be completed by visiting the galleries of the central and eastern blocks, where the specimens are arranged according to the organs affected. In ascending to them it would be pointed out that a staircase descends to the basement in which is housed our unequalled odontological collection, where amongst the specimens which came to us from the Odontological Society are Hunter's own classical preparations.

And now I should bid my guest adieu, feeling, if not saying, that while in his writings there may be some things hard to be understood, here in our Meseum is recorded in unmistakable language the record of thoughts and ideas that is impossible to misapprehend.

SUGGESTED ANATOMICAL AND PATHOLOGICAL INSTITUTE.

Thus, in an imperfect way, I have tried to show what the Royal College of Surgeons has done, and hinted at the certainty that some day the Museum will have to be enlarged. Now let me put before you a vision of the future. Ought not this great city to have an Anatomical and Pathological Institute? Our University has again, by collision, passed into the nebulous state, and we know not in what form, nor, indeed, in what orbit or orbits it may finally revolve. It may be anticipated with confidence that it will emerge as a life-supporting globe or double star with a more equable temperature than at the present moment. Money is to be had for proper asking, and a site is generally obtainable when it is required. Can you not see such a noble institute close at hand, forming a part of a really living University, and also in close connexion with our College, attracting workers from all over the world, to utilise the vast material the Museum contains? It would strengthen the feeble bonds which at present unite us to the University, and supply a long felt want of the Medical Faculty. It would offer opportunities for original research in human and comparative anatomy and in pathology; and in its theatre lectures on advanced subjects would be delivered *urbi et orbi*.

RECENTLY DECEASED MEMBERS OF THE COUNCIL.

The terms of the bequest under which these orations are given instruct the speaker that "such Oration should be expressive of the merits in Comparative Anatomy, Physiology, and Surgery, not only of John Hunter, but also of all such persons, as should be from time to time deceased, whose labours have contributed to the improvement or extension of Surgical Science."

This would be an impossible task, for the whole world is apparently included in the purview, but according to custom and by inclination I must say a few words about two friends and colleagues on the Council whose vacant places we deplore.

Clinton Thomas Dent, an all-round original and successful surgeon at Hunter's own hospital, was Vice-President at the time of his unexpected death last summer. He had no specialism in medicine, and he will rather be remembered by his numerous friends for his many-sided character, multifarious attainments, and sterling worth than for striking additions to surgical practice or literature, and yet his contributions to them were neither few nor unimportant.

Sir Henry Trentham Butlin, my immediate predecessor, on the other hand, was well known as a surgical pathologist, whose chief labours were devoted to the treatment of, and the elucidation of the cause of, cancer, a subject to which it may be said he devoted his last breath. Those who can recall this day four years ago, when his oration was delivered in perfect English and without a note, will agree that he was a finished orator. We on the Council knew him as an admirable man of business, who wisely conducted the affairs of this College, as a man of the highest integrity, a pleasant companion, and a faithful friend.

COMPARISON OF LISTER AND HUNTER.

But beyond and above all the other leaders, or men in the ranks, who have passed away during the last two years, is Lister, who by common consent is the greatest—that is, the most thoughtful and original—surgeon since Hunter's time, one who more than any of his predecessors was influential in revolutionising both the science and the art of surgery. It is not the occasion to enter upon a survey of Lister's work, but it may be interesting to consider the influence that Hunter had upon him, and briefly to compare the two men.

The first time I heard the name of John Hunter was in my youth during one of Lister's vacations, which he often spent at his father's house. The subject he was describing is forgotten, but the name impressed itself upon my young memory, and many a time in after years have we, who were closely associated with him, heard this name recalled with reverence and admiration. Occupying a prominent place in his study was Sharp's engraving, bequeathed to him by Mr. Syme, and now my treasured possession, as is also the edition of Palmer's Life, which is marked in many places. These passages show that Lister was studying this book at the time he was making his early observations on coagulation of the blood. Indeed, a precise date may be fixed by a pencil note to the account of "a gentleman with violent inflammation in one of his eyes and whose blood was extremely sizy, though the coagulum was very loose." The note is "No excess of fibrin in this buffed blood apparently. J.L. /58." Other marks are opposite references to inflammatory fever; the principles of bleeding, and especially their possible dependence upon continuous sympathy; and local diseases cured by sympathy, as by the application of an irritating medicine applied to some other part which this diseased part sympathises with There are several in the lecture on aneurysm; indeed, there are exclamation marks opposite some references to hydrostatics And similar annotations are met with on the lecture on Fistula and elsewhere

It might be wondered what were the points of attraction between men in many ways so different Certainly Lister possessed none of Hunter's mania for collecting He had, indeed, what he called his museum, one or two bread pans containing specimens, no doubt of great value, and familiar to the succeeding generations of attenders at his lectures But his shelves and cupboards were filled with more transitory things—flasks and test tubes and the materials for experiment Lister bought no costly works of art, and was content with early or late Victorian furniture, and though he often adopted Hunter's generous but confusing method of leaving the amount of the fee to the patient's decision, he did not spend the proceeds in the same reckless way

The points in Hunter's methods which Lister seemed most to admire and adopt were, first, that he appears to have taken nothing for granted No matter how revered the teacher, how sacred the tradition, Hunter and Lister both asked themselves whether the evidence was sufficient to support the theory or warrant the treatment Perhaps they would not have liked to be called sceptics, but in scientific matters they were, and it is the only safe position for a scientific man to adopt, though it may not indicate the path of worldly wisdom to the practitioner

Illustrations might be given in Hunter's operation for aneurysm, or his observations in fistula in ano, or in Lister's amputation of the thigh, his excision of the wrist, or his methods of treatment of varicose veins or hydrocele But there is no need to multiply examples The whole story of *Lister's discoveries and of the modifications in ordinary* surgical practice which he introduced testifies to the truth of this assertion

But, secondly, the most striking resemblance between them is their habit of referring everything to experiment Their lives were occupied in testing by means of experiment every problem that presented itself They were, indeed, both of them, ideal inductive philosophers

It seems in some quarters to be considered that an inductive philosopher is debarred from framing for himself hypotheses, but this I conceive is not the case Did not Bacon himself say, "Vaga experimentia mera palpatio est"? Such an idea would seem to imply that the followers of that great thinker experiment at large, and only accept the results of those promiscuous excursions The difference, however, between them and the deductive philosophers is that the latter found their creed on deduction from unverified postulates, whereas the former require proof of the correctness of the premises before they complete the syllogism No great Baconian can get on without hypotheses, but he is ready to reject those that are not supported by his experiments Are not Pasteur and Darwin proofs of the truth of this statement?

There is an interesting appreciation of Hunter's character in Buckle's "History of Civilisation in England" Buckle is almost labouring the point that the trend of thought in Scotland in the eighteenth century was deductive and that in England inductive, and is arguing that Hunter was a sort of hybrid

[illegible] lon in 1748 Newton had been
[illegible] ish people absorbed in practical
[illegible] ical
at
to
efit
[illegible]
Scotchman he [illegible] ir
ticular facts, as [illegible] he
opposite plan of [illegible]

It is rash to differ from so great an authority, but, as a matter of fact, did Hunter really get his mind down on methods of reasoning and such abstruse questions during his idle youth at Long Calderwood, when he cared much more for country sports than for books, or whilst helping his convivial brother in law, Buchanan, in his carpenter's or [illegible] formation of his mind it must have come from his brother William But in reading much of his writings and in trying to assimilate the spirit in which the Museum was planned, I feel that Buckle has overstated his case, and that Hunter was essentially an inductive philosopher

And so was Lister His whole life was made up of experiments Any time that could be filched from practice or unavoidable public and private duties was spent in his study, investigating for himself such subjects as the coagulability of the blood, the growth of micro organisms, the properties of antiseptic substances, blood pressure, and so forth, and it is interesting to notice how he called in aid for the solution of his special problems a well grounded knowledge of botany, zoology, chemistry, and physics, subjects of which it is becoming too much the habit nowadays to minimise the importance

But there are fundamental differences between them, of which the most important (to speak with all respect) is that Hunter's work is the more diffuse He seems to fly from one subject to another, as if he were unable to resist the temptation to investigate everything that came in his way It is as though what has been referred to above as the spirit of the collector inspired his more serious work, and so he has left a record of an almost incredible number of problems either completely or partially elucidated

Lister, on the other hand, did not yield to this temptation if he felt it Starting on the narrow path upon which Providence had placed him he followed it till it broadened and straightened out into the great highway that led him to his goal Not that he denied himself the pleasure of occasional explorations of tempting by paths, but what he gained from these excursions was always utilised to corroborate and support him upon his journey And thus it comes about that Lister's fame rests chiefly upon the one great achievement of his life, whilst the lesser and more subsidiary ones are by many forgotten or ascribed to others, whereas it is difficult to mention one or even a few of Hunter's labours which stand out in glaring predominance above the rest

Of less importance but equally striking are the differences between them in temperament, culture, and manners Hunter was imperfectly grounded in general education, a small reader, abrupt not to say rough in his conversation, which was flavoured with a full share of the impetuous vocabulary of the eighteenth century Though generous he was impatient, though on the whole a good friend, he was somewhat inconstant, and his mind was so fully occupied with his work that more solemn subjects had no chance of consideration

Lister's mind was well stocked with classical and other learning, and his library was lined with carefully studied books He was gentle and courteous, and though full of humour he could not abide even those relics of coarseness which survived in "polite conversation" in the nineteenth century He was always ready to make allowance for the incompetence of those who did their best, he made no enemies, and his position as regards more serious matters was a very different one from that of his great predecessor

Both, however were fond of argument and neither in the course of it could easily brood opposition Verily it is a matter of thankfulness that they lived at different epochs It is well that Lister was able to contemplate Hunter's many great qualities and his few obvious defects through the modifying mists of the intervening years

CLOSING REMARKS

I have spent the last year in an atmosphere permeated by the spirit of John Hunter, I have had the privilege of passing the best years of my life in the closest intimacy with Lister, and I often ask myself in what way a genius surpasses the average man After a day passed in the company of such a one, and after meditating on any particular thing that he did, the ordinary man might fancy that there was nothing in it he could not have done equally well himself, and yet the life's performance is so different! The individual touches of the brush might conceivably be made by anyone, but only the artist can produce the picture. That, of course, depends upon the master mind which coordinates the details, making them minister to the result We cannot attain to that, and it is the consciousness of this superiority of the great that makes the position of ambitious mediocrity so painful. But though we cannot reach to the height of Lister or of Hunter we may make our lives more useful by imitating their extreme diligence, their accuracy, and their habit of finishing whatever they were engaged upon before turning to the next matter; by not shirking the long days of labour and nights devoid of ease, or spending too much of our time on pleasures and indulgences.

The problem of life to Hunter was the still unsolved riddle of its meaning and of its origin. Lister was content with the belief that at the present day there is no spontaneous generation. Had he doubted the truth of this doctrine he might possibly have had misgivings as to the truth of the gospel that he preached. Fortunately he did not doubt, for he was a man of firm convictions.

But after all, whether chemical changes are now and always converting dead inorganic substances into living protoplasm is, for practical men, no more important than the more abstruse question as to whether matter is composed of atoms or vibrations. Life for us has another meaning; whilst the blood is moving in our bodies, as John Hunter said, we have life, and the problem for us, taking him for an example, is not simply to keep alive, but to live well.

> Nicht dass man lebe, sondern wie,
> Ist Mannes wurd'ges Streben;
> So lang mir Leben Gott verlieh,
> Will ich's lebendig leben.

TRANSMISSION TO MONKEYS OF VIRUS OBTAINED FROM ENGLISH CASES OF POLIOMYELITIS.

By JAMES McINTOSH, M.D. ABERD.,
BACTERIOLOGICAL LABORATORY, LONDON HOSPITAL (PROFESSOR WILLIAM BULLOCH);
AND
HUBERT TURNBULL, D.M. OXON.,
DIRECTOR OF THE PATHOLOGICAL INSTITUTE, LONDON HOSPITAL.

ACUTE anterior poliomyelitis, or infantile paralysis, has, during the last few years, been occupying the attention of the medical world on account of the epidemics of varying intensity which have occurred in Europe and North America. Prior to 1909 the infective nature of the disease was based on epidemiological and pathological evidence; in that year, however, Landsteiner and Popper[4] demonstrated the correctness of the deduction by producing the disease in monkeys by the inoculation of an emulsion of the spinal cord of a fatal case of infantile paralysis. The possibility of transmitting poliomyelitis to monkeys has been confirmed by Knoepfelmacher,[3] Strauss and Huntoon,[12] Flexner and Lewis,[1] Levaditi and Landsteiner,[5] Leiner and Wiesner,[7] Römer,[10] and Thomsen.[13] Landsteiner and Popper failed to propagate the disease in series, but Flexner and Lewis, and later Landsteiner and Levaditi, showed that the disease could be propagated in series in the monkey.

Up to the time of writing no one has recorded the successful inoculation of the virus in Great Britain. Levaditi in Paris, however, managed to transfer the disease to monkeys from pieces of cord sent to him by Dr. M. Gordon.[6] Dr. Gordon's material was obtained from cases which occurred in an epidemic in Devonshire and Cornwall in 1911. Whether the English virus is absolutely identical with the continental and American virus has yet to be demonstrated.

In the district (East London and Lower Essex) embraced by the London Hospital acute anterior poliomyelitis has been increasing in prevalence during the last three years, and from June to October, 1912, over 30 cases were admitted into the hospital as in-patients. According to Dr. E. G. Fearnsides, medical registrar, a considerable number of cases of herpes zoster were observed simultaneously with the cases of infantile paralysis.

This paper deals with the inoculation into monkeys of material from four cases of poliomyelitis which, with one exception (Case 1), occurred in the London Hospital district.

Inoculation technique.—In every instance the monkeys were inoculated intradurally as well as intraperitoneally with the emulsions of cord. Pieces of the spinal cord and brain, unless otherwise stated below, were on their removal from the body transferred to a bottle containing a 33 per cent. solution of glycerine in saline and were kept in the ice chamber till required. For the inoculation of a monkey about 1 grm. of cord was placed in a conical glass, cut into as small pieces as possible with a pair of scissors, pounded up with a glass rod, and finally rubbed up with about 6 c.c. of saline. The larger particles were allowed to settle, and then the emulsion was drawn into a syringe. In practice it was found better to use a 10 c.c. record syringe for the intraperitoneal injection, and a 0·5 c.c. syringe with a finer needle for the intradural inoculation. Under an anæsthetic (ether) a small incision about ¼ in. long was made down to the periosteum just above the superciliary ridge and just outside the middle line. A small hole was then made with a drill (diameter 2 mm.), a fine needle introduced, and 0·5 c.c. of the emulsion injected. At the same time 4 to 5 c.c. of the emulsion were injected into the peritoneum.

The clinical histories and pathological reports of the cases from which the material for inoculation was obtained are detailed below.

In order to abridge the description of the microscopical changes it is advisable to refer here to some of the salient features found in these cases and in other cases of poliomyelitis which have been obtained from the neighbourhood in the last two years. Definitions can thus be given of the terms employed.

General characteristics of infiltration.—Infiltration is found in the meninges, especially the pia, in the lymphatic sheaths of the vessels, and in the nervous tissue external to the sheaths. It may be present in the nerve roots and their ganglia. In the case of many of the larger vessels within the cord and brain the arteries and veins are enclosed in a common lymphatic sheath which is a direct extension of the pia. This is seen very clearly in the case of the large branches of the arteries and veins which enter the cord from the anterior fissure. The smaller vessels and at any rate the larger capill [illegible] proper to themselves. Where smaller [illegible] vessels enclosed in a common sheath, the [illegible] sheaths are seen to be in direct continuity. Both these "common" and "individual" lymphatic sheaths will be referred to as "adventitial sheaths," a distinction only being made in cases in which there is a marked difference in the cells of their respective infiltrations.

The infiltration of the substance of the cord or brain external to the collagenous membrane which bounds the adventitial sheaths may be called the "extra-adventitial infiltration." This is seen in three forms. 1. As a more or less evenly distributed infiltration in the glial matrix. 2. As groups of cells packed together in areas in which glial fibres are absent. The former infiltration will be referred to as "diffuse," the latter as a "focal c [illegible] dition to these two forms of extra-adve [illegible] of cells round, and in some cases withi [illegible] otoplasmic processes requires special me [illegible] uronophagia" Some of the "focal aggregations" doubtless represent collections of "neuronophagocytes" whic [illegible] placed degenerate nerve cells Their distribution [illegible] ut in many aggregations there is no evidence of th [illegible] lie, as a rule, in close relation to small capillaries, others occupy extensive areas. A zone of infiltration is frequently seen round a delicate capillary in which no adventitial sheath is visible. Such perivascular infiltration is doubtless the precursor of many of the "aggregations."

The character of the cells in the infiltrations.—The cytology of all the cases examined is in general very similar. The character of the infiltration differs, however, in each of the above-mentioned sites. Striking variations are also found in the character of the cells, and more particularly in the relative number of the different cells, in the same sites in different cases and even in different portions of the central nervous system in individual cases. In order to compare different cases it is necessary, therefore, to enumerate the chief types of cells which may be found, and to furnish them with names. For the examination of the cells the stains of Jenner and Unna-Pappenheim have been chiefly employed.

The cells in the infiltration of the adventitial sheaths.—The majority of the cells have a basophile protoplasm devoid of specific granules. Although there appear to be transitional forms between these non-granulated cells, there are four types which can be identified with little difficulty. Incidentally it may be mentioned that the recognition of these types is of importance in determining the origin of the cells.

1. The majority of the cells are usually closely similar to the *small and large lymphocytes* of the blood. Large forms, as a rule, predominate. The smaller ce [illegible] ingle nucleolus, the larger may have two or ev [illegible] e protoplasm of the larger cells is usually more [illegible] contains some large vacuoles.

2. Closely allied to these are cells which on an average have a surface area equal to from three to five red corpuscles. Their protoplasm is intensely basophile and coarsely reticulated. The nucleus contains large, oval, very conspicuous nucleoli; three nucleoli are usually seen These cells are similar to cells present in the germ centres and in the rest of the lymphadenoid tissue of lymphatic glands. Deeply basophile cells containing karyokinetic figures are also found in many cases; these cells are usually of about the same size as the cells under discussion. In the absence of a less compromising term the cells of this type may be called "*lymphoblasts.*"

3. Easily distinguished from the above is a cell which averages in surface area three red corpuscles. It has a very faintly basophile, finely reticulated protoplasm. The nucleus has a much more delicate membrane and more delicate fibrils of chromatin than in the cells already described. The chromatin is arranged in a net which may be very similar to that of the fixed cells of the adventitial sheath, but is as

a rule of wider mesh. One to three small nucleoli may be recog

CASE 1.—Female, aged 14 years, of St. John's Wood. The history of the case was as follows:—

History.—On Saturday, Dec. 24th, 1910, the brother of the patient, aged 17 years, complained of being unwell. On Sunday he still felt out of sorts, refused to go to church, and said he had difficulty in breathing. Later in the day his symptoms became alarming, and the doctor was called in and diagnosed œdema of the lungs. The breathing became more and more difficult, and he died at 2 A.M. on Monday, after

, aged 14 years, said she

of bed; the doctor was

she had difficulty in

ed at 7 P.M. that evening

ed. Death took place at

as made on Dec. 29th. Nothing abnormal was found except that the grey matter of the cord was very congested.

About $1\frac{1}{2}$ inches of the cervical cord of this case were obtained from Dr. Henry Head.

be pale or pyknotic. There is an increase in fixed and free

The piece of cervical cord was removed aseptically and kept 11 days in the ice-chest under aseptic conditions, then an emulsion of the cord in normal saline was made and injected intradurally and intraperitoneally into three monkeys (Macacus rhesus). No rise of temperature or any bad effects were observed in any of the animals, and a histological examination of pieces of the brain and cord of one of them showed no alteration suggestive of poliomyelitis.

CASE 2.—A boy, aged eight months, of Leyton, N.E. The patient was admitted to the London Hospital under the care of Dr. Otto Grünbaum on Oct. 6th, 1911, 14 days after the onset of illness, and died on Nov. 20th, 1911.

and admitted.

tonic, but not wasted. N

passive movements of the

could not be obtained, and there was no evidence of involvement of cranial nerves. The heart and lungs were clear; the temperature ranged between 99·8° and 93° F.

Under treatment with massage and passive movement the right arm and leg improved considerably; the left leg, however, showed little improvement, and wasted. On Nov. 13th the child developed nasal and faucial diphtheria, from which he died on the 20th.

Summary of necropsy (No. 1188; Nov. 21st, 1911).—Bronchopneumonia. Nasal, pharyngeal, and laryngeal diphtheria. Healing polio[illegible]

[illegible] *tral nervous system.*—The dura was firmly adherent to the calvaria, which averaged about two millimetres in thickness. The cerebral venous sinuses contained fluid blood [illegible] The pial vessels of the brain were injected. [illegible] flattened. The cisternæ basalis and magna [illegible] by clear fluid. Before complete exposure [illegible]ninæ of the first thoracic vertebra were removed, and the posterior roots of the first thoracic segment were ligatured. The subarachnoid space over the termination of the cord contained about one drachm of clear fluid. The inner surface of the dural theca was smooth and glistening. The leptomeninges were thin and transparent.

The following appearances were seen on section.—In the cerebral hemispheres the cortex was flat and of a uniform purplish-grey colour; the medulla was white. No abnormality was detected in the basal ganglia, pons, and bulb, save a minute hæmorrhagic dot in the centre of the decussation of the pyramids. In the greater part of the cord the grey matter was grey and the white matter white. In the fifth cervical [illegible] horn was pink; vessels were visible in the [illegible] greater part of the cervical region. Vessels [illegible] matter of the third and fourth lumbar segments; the anterior horn on the left side of the fourth lumbar segment became slightly sunken.

Segments were removed from the cervical, thoracic, and lumbar region for inoculation.

Microscopic examination.—The fourth lumbar, seventh thoracic, and seventh cervical segments, portions of the *medulla, pons, cerebellum, right and left* [illegible], centre of *right and left Rolandic regions*, and [illegible] were fixed in 4 per cent. saline formalin and embedded in paraffin. Other portions were placed in Müller's fluid for Marchi's method. Sections of the 15 portions fixed in formalin and embedded in paraffin show, with the exception of œdema of the leptomeninges of the cerebrum, no abnormalities save in (1) the fourth lumbar, and (2) the seventh cervical segments.

(1) In the *fourth lumbar segment* there are a very few lymphocytes in the pia, especially in the neighbourhood of the veins. There is a conspicuous, large, round, pale area of softening in the ventrolateral portion of the left anterior horn. Nerve cells are still present in the mesial portion of the anterior horn and the base of the posterior horn. The adventitial sheaths of some of the vessels within the left anterior horn are infiltrated. The cells are almost all very large, vacuolated, fat-granule cells; they have either a large twisted, pale nucleus showing a [illegible] *chromatin, or they have a smaller, oval,* [illegible] which the structure is obscured. There [illegible] In the extra-adventitial tissue there are [illegible] similar fat-granule cells and a marked excess of fixed and free glial cells.

On the right side a few nerve cells still remain in the lateral groups. A similar infiltration of the adventitial sheaths and of the extra-adventitial tissue is present. Fat-granule cells outside the adventitia are rare on this side, and there are few free glial cells.

(2) In the *seventh cervical segment* there is a great diminution in the number of nerve cells in both anterior horns. On both sides the lateral, and especially the ventrolateral, groups have suffered most; the lateral groups on the right side are almost completely destroyed. There is a slight infiltration of the sheaths of a few vessels in both anterior horns by fat-granule cells and occasional lymphocytes. In the extra-adventitial tissue there is a marked excess of fixed and free glial cells, the excess being slightly greater on the right side.

In neither segment are leucocytes containing specific granules, or plasma cells present in the infiltrations.

Pieces of the cervical, thoracic, and lumbar cord were emulsified in normal saline and injected into a Macacus rhesus monkey, but although the monkey was observed over a long period of time no bad effects were seen.

CASE 3.—A boy, aged 18 months, of Stepney, E. The patient was admitted to the London Hospital under the care of Dr. Cecil Wall on the evening of Sept. 27th, 1912, and died 13 hours later.

History.—The patient was the second of two children. His only brother was alive and healthy, aged 4 years. His father and mother, who had been married five years, enjoyed good health. There was no family history of tuberculosis, rheumatism, or nervous disease. The patient was a fine, healthy baby at birth. He was breast-fed for 12 months, and had never had any previous illness. On Sept. 23rd, *four days before admission*, the child was noticed to be cross, feverish, and ailing. On the evening of this day he *vomited*. Since the onset of the illness he had been drowsy, thirsty, and constipated. No local weakness had been noticed by the mother, who had nursed the child. On Sept. 27th, the day of admission, about 5 P.M., the *mother noticed* that the child's breathing suddenly became embarrassed and that his colour altered. At 7.30 P.M. the child [illegible]

On admission the child was a fine, [illegible]-looking baby. The face was flushed, the lips blue, the extremities greyish blue. From time to time under observation, in attacks, the colour of the child was seen to become greyer and more ashy. He cried seldom, and then the cry was feeble. Over the region of both shoulders was a macular eruption, which had not been noticed by the mother.

Cranial nerves.—There was no absolute palsy of any eye muscle, but under observation dissociated movements of the eyes were seen. The face was symmetrical. The tongue could be protruded and the child swallowed readily. The trapezii and sternomastoid muscles acted poorly.

Motion.—Both arms were flaccid and paretic, and under observation were not moved voluntarily. The left leg was paretic and undertoned; the right leg was seen to be drawn up spontaneously on occasion, and it could be induced to retract reflex[illegible] intercostal muscles on both sides were [illegible] spiration was carried out entirely by [illegible] The respiratory movements were acc[illegible] *movements*" of the larynx and "tooth[illegible] jaws and lips. On the lips was froth. There was no stridor. The muscles of the erector spinæ group were all paralysed. The child when picked up by the waist fell backwards like a formless mass.

Reflex movements were elicited from the face and right leg when these were pinched.

Reflexes.—The knee-jerks could not be obtained on either side. The plantar reflexes on each side were flexor in type. The abdominal reflexes could not be elicited. Doubtful arm-jerks were obtained. Kernig's sign could not be elicited. The pupils reacted readily to light.

[illegible] rate of the pulse was [illegible] was 64 per minute. [illegible] normal dulness over [illegible] ses produced in the throat.

The child died at 8.30 A.M., 13 hours after admission, from increasing respiratory difficulty. During the night preceding death he had five or six attacks of grave dyspnœa accompanied by universal greyness, much retraction of the lower ribs, and an increased degree of cyanosis; he swallo[illegible] these produced no improvement.

Summa[illegible] *Sept. 30th, 1912).—"Respiratory failure.* [illegible] *Collapse of lower and posterior portion of right lower lobe and of inferior margins of both lobes of lungs. Tuberculosis; a few caseous areas and caseous miliary tubercles in the glands in the central and upper tiers of the mesentery; submiliary granulation tubercles in spleen (2 oz.). Great congestion of liver (15 oz.), kidneys (3 oz.), stomach, and intestines. Large thymus (35 grm.), lingual, faucial, and pharyngeal tonsils; general enlargement of lymphatic glands; large Peyer's patches and solitary follicles in intestine. Muco-pus in right mastoid. A very fat, well-developed child."*

Macroscopic examination of central nervous system.—The calvaria was 1 to 2·5 mm. thick, and hard to cut with the knife. The dura was adherent only in the region of the anterior fontanelle; its inner surface was smooth. On removal of the dura the hemispheres showed flattened convolutions with narrow, shallow sulci. The subarachnoid veins were engorged. The surface of the brain was in general of a dull, rosy-grey colour, with numerous bright red, small vessels coursing over the convolutions. There was a small, diffuse, subarachnoid ecchymosis on the left frontal pole, and a few minute petechiæ on the orbital surface of both frontal lobes. The lateral ventricles each contained from 10 to 20 minims of clear fluid. Before exposure of the spinal cord the laminæ and spine of the first thoracic vertebra were removed, and the posterior roots of the first thoracic segment were ligatured. The subarachnoid space over the lumbar region was much distended by slightly opalescent, faintly blood-stained fluid. The veins of the vertebral canal were greatly engorged. The arachnoid membrane was thin and transparent.

The following appearances were seen on section.—In the cerebrum the cortex was dark, purplish-grey, firm, flat, and sharply defined from the white matter. The white matter was somewhat dry and showed numerous injected vessels from which blood oozed spontaneously. The grey matter of the basal nuclei, pons, and medulla had a purple tint. The anatomical pattern in the brain and bulb was normal; there were no petechiæ. The grey matter of the cervical cord was dark, slaty-grey, and showed injected vessels; the grey matter of the lumbar cord bulged and showed numerous delicate, injected vessels.

The fifth, sixth, and seventh cervical segments and the third lumbar segment were removed and placed in 20 per cent. glycerine for inoculation.

Microscopic examination.—The third lumbar and eighth cervical segments were fixed in 4 per cent. saline formalin, embedded rapidly in paraffin, and examined for the confirmation of the diagnosis.

(1) In the *third lumbar segment* the posterior roots, within the arachnoid space, and their vessels are free from infiltration. There is a little infiltration round the vessels and within the neural sheath of the anterior roots. There is great infiltration of the pia in the antero-lateral regions and [illegible] region. The prolongation of the pi[illegible] its continuation round the large branches of the anterior spinal arteries and veins within the cord are densely infiltrated. The adventitial sheaths of almost all the vessels which pass from the pia through the white matter, and of the larger vessels within the grey matter, are infiltrated. The majority of the capillaries within the grey matter show no adventitial infiltration. An epispinal space is only present in a few places; it is not infiltrated. Definite perivascular canals are very seldom present. When present they render the adventitial nature of the infiltration conspicuous. They frequently contain hyaline spheres, but rarely contain any cells. The vessels in the meninges and grey matter are engorged. There is a large patch of extra-adventitial infiltration in the white matter, close to the periphery of the cord, on the ventral side of the entrance of the right posterior root. There is slight diffuse infiltration in the ventral portion of the lateral white columns. Diffuse infiltration is extreme in the anterior horns and marked in the bases of the posterior horns. It is greatest in the right anterior horn. In this horn there is much vacuolation, the tissue being obviously softened. In the left horn there is also vacuolation, but this is more focal. In both anterior horns are conspicuous "cellular aggregations." In both anterior horns there is extreme degeneration and necrosis of the nerve cells. Many cells have entirely disappeared. In the posterior horns the majority of the nerve cells retain an angular shape, but complete or incomplete tigrolysis is present. Neuronophagia is in places very marked.

Cytology.—In the infiltration of the common sheath of the vessels in the anterior fissure and of their large intraspinal branches the majority of th[illegible] larger forms being most numerous. Th[illegible] There are many hyaline cells. A few [illegible] Many are phagocytic, containing pyknotic nuclear remnants. In the infiltration of the individual sheaths of the smaller vessels hyaline cells are relatively more abundant.

[illegible]

destruction on the left side. As in the lumbar segment, scarcely a single neutrophile leucocyte can be found outside the lumen of the vessels.

(3) *Sacral and upper and lower thoracic segments; medulla, mid-brain, and left central region of cortex.*—In order to obtain an idea of the extent of the lesion blocks containing these areas were cut and stained. Different degrees of characteristic infiltration were found in all.

The pieces of the lumbar and cervical cord were kept in 20 per cent. glycerine for seven days at room temperature, and then emulsified in saline and injected into a Macacus rhesus monkey on Oct. 4th, 1912. Eight days later the monkey developed facial paralysis, and two days later paralysis of the right leg. On Oct. 15th the symptoms were more marked, and the animal was killed by coal gas.

Strain A, Passage I.—Male Macacus rhesus No. 4.

Summary of necropsy (Oct. 15th, 1912).—"Poisoning by carbon [illegible]

[illegible] There were [illegible]

[illegible] rfectly transparent, and there [illegible] ninges in the Sylvian fissures. [illegible] cord the laminæ and spine of [illegible]

[illegible]

Segments from the cervical, thoracic, and lumbar regions were removed for inoculation.

Microscopic examination.—In order to verify the diagnosis three segments—the third lumbar, sixth thoracic, and third cervical—were embedded in paraffin and examined prior to a full microscopic investigation of the organs.

[illegible] n the antero-lateral [illegible] Within the anterior [illegible] on of their sheaths. [illegible] the largest and most numerous [illegible]

necrosis. Several [illegible]

granular masses surrounded and infiltrated by numerous round cells. There are also a *few cellular aggregations which do not appear to be connected with neuronophagia.*

Cytology.—The majority of the cells of the adventitial infiltration are lymphocytes. Small lymphocytes are present, but the average cell [illegible] A few lymphoblasts are [illegible] karyokinesis. There are [illegible] etween the hyalines and [illegible] Some of the [illegible] deeply basoph [illegible] cells. There [illegible]

[illegible] a *few vessels close* [illegible] nerve cells of the [illegible] and irregularly [illegible], prevents stress

[illegible]—There is a little infiltration round the left posterior root and in the [illegible]

[illegible] diffuse infiltration were found in the *sacral cord, brain stem,* and *cerebral cortex.* The greatest *diffuse infiltration was found in the region of the nucleus of the seventh* cranial nerve on the left side.

CASE 4.—A boy, aged 2¼ years, of Bethnal Green, E. This patient was admitted to the London Hospital, under the care of Dr. Robert Hutchison, at 3 P.M. on Oct. 24th, 1912, and died at 1 A.M. on Oct. 25th.

[illegible] illness.

[illegible] pain on movement and of great thirst. At 8 A.M. on the day of admission (*fifth day of illness*) he suddenly became worse, he became weak and languid and no longer moved his limbs. At 11 A.M. he started to breathe badly and became blue. Four hours later he was admitted to hospital.

The other children at home were all well, and the patient's mother had no knowledge of any other children ailing at the same time, and did not know of any other cases of paralysis amongst her relations. [illegible]

His mentality was unimpaired. He had no fits. There had been no vomiting since the 20th, the day of onset.

Cranial nerves.—The eyes moved naturally. The pupils reacted briskly to light and on accomm [illegible] movements of contraction and dil [illegible] there was no change in the amour [illegible] face was symmetrical and move [illegible] protruded well; it was coated [illegible] swallowed readily. The discs and fundi were normal. Hearing was unaffected.

Motion.—The legs, lower intercostal muscles, and belly muscles were completely paralysed, and all the back muscles below the clavicles were atonic. The child arched backwards when lifted by the middle of his back. The right arm below the shoulder was paretic; the left arm could be moved slightly. On both sides the diaphragm acted fairly well. The two upper intercostal muscles seemed to contract synchronously with the diaphragm and the sternomastoids during inspiration. No loss of sensation could be detected.

The knee-jerks, ankle-jerks, and abdominal reflexes could not be elicited on either side. On attempting to elicit the plantar responses a slight downward movement of the toes occurred. The skin over pressure points readily developed an erythema which disappeared in about five minutes after the removal of the pressure. There was incontinence of urine without retention. The child died 10 hours after admission from respiratory failure.

Summary of [illegible] *5th, 1912).—"Respiratory failure. Acute* [illegible] *lapse of lower two centimetres of right lo* [illegible] *of liver; great congestion and œdema of l* [illegible] *us gland in lower tier of mesentery, nearer cæcal border. Slight p* [illegible] *Mucous catarrh of nose.* [illegible] *d well-nourished child* [illegible]

Macroscopic examination of central nervous system.—The fontanelles were closed. The dura was adherent to the calvaria along the superior longitudinal sinus. The superior longitudinal and other venous sinuses contained fluid blood. The convolutions on the cerebral hemispheres were slightly flattened, the sulci being somewhat shallow. The brain appeared and felt large and bulky. Each lateral ventricle contained about half a drachm of fluid, which appeared slightly opalescent when drawn up into a pipette. The laminæ and spine of the first thoracic vertebra were removed, and the posterior roots of the first thoracic segment were ligatured before exposure of the whole cord. On incision of the dura over the lumbar region the arachnoid was bulged outwards by about an ounce of fluid. This fluid, when examined in a test-tube, was seen to be slightly milky. The inner surface of the dural theca was smooth; it showed one pin-point hæmorrhage at the level of the emergence of the seventh left thoracic root.

The following appearances were seen on section. The cerebral cortex in the right central region was of a purplish colour and sharply defined from the white medulla; numerous fine vessels were visible in both cortex and medulla—they were more conspicuous in the latter. In the mid-brain the tissue was firm, the grey matter was grey; there were visible vessels in the crura and tegmentum. There was no injection of a cut surface through the centre of the pons. At the level of the centre of the olives the grey matter in the floor of the ventricle was purple and a few injected vessels were present. The cut surface of the second cervical segment was flat and firm; its grey matter was grey; blood oozed from small vessels. In the fourth cervical segment the grey matter was pink and showed numerous injected vessels. The right branch of the anterior spinal artery was either greatly injected or surrounded by hæmorrhage. In the fourth cervical segment the grey matter was pink and dotted with injected vessels; the cut surface was flat. In the seventh segment the surface bulged slightly, the [illegible] blurred, and numerous engorged vessels were [illegible] d white matter; there was a punctiform [illegible] matter on the right side. The grey matter of the third thoracic segment was paler pink; injected vessels were visible therein. In the eighth thoracic segment injection of vessels was very marked on the right side. The grey matter of the first lumbar segment was slightly swollen and pink and contained injected vessels. In the second lumbar segment the grey matter was pinkish-yellow, softer and more swollen; it contained injected vessels. The cut surface of the fourth lumbar segment was injected and bulged considerably.

A large slice from the centre of the right hemisphere together with the fourth and seventh cervical, the third and eighth thoracic, and the second and fourth lumbar segments, were placed in 33 per cent. glycerine for inoculation.

Microscopic examination.—Portions of the fourth lumbar, twelfth thoracic, and sixth cervical segments were fixed in 4 per cent. saline formalin and embedded in paraffin for immediate examination.

(1) *The fourth lumbar segment.*—There is a little infiltration of the arachnoid and of the adventitia of the vessels accompanying the spinal roots. The pia is markedly infiltrated in places on the anterior and lateral aspects of the cord. The pial extension in the anterior fissure is infiltrated; the infiltration is greatest in the dorsal extremity of the fissure and in the common sheaths of the vessels branching from the fissure. There is also infiltration of the sheath of almost all the vessels which pass through the white matter, and of the sheaths of numerous vessels within the grey matter. There is no adventitial [illegible] illaries in the anterior horns. There is a very [illegible] of the anterior horns. There is also consider- [illegible] of the posterior horns and of the white matter immediately surrounding the anterior horns

In the anterior horns there are many cellular aggregations; on the left side these are very large and occupy extensive areas. Engorgement of the vessels in the grey matter is very conspicuous, and there are some small hæmorrhages. The nerve cells in the anterior horns are almost all completely necrosed and represented by rounded hyaline masses; in the posterior horns they show varying degrees of degeneration, and here slight neuronophagia can be seen. The central canal is empty.

Cytology.—In the infiltration of the sheaths the majority of the cells are lymphocytes. Lymphoblasts are not numerous. Hyalines are present in considerable numbers, and there are a few phagocytes. Pyknotic bodies are not numerous. There are considerable numbers of eosinophile leucocytes; neutrophile leucocytes are exceedingly scarce. One plasma cell was seen. In the diffuse infiltration there are large numbers of fixed and free typical glial cells and elongated glial cells. There are also many polyblasts. There are very few neutrophile leucocytes. There is a considerable number of pyknotic bodies, and some of these can be recognised as remnants of [illegible] few eosinophile leucocytes are present. I [illegible] the cells ares almost all polyblasts. Many [illegible] others contain pyknotic nuclear remnant [illegible] leucocytes can be found; they are degenera [illegible] the nerve cells are free typical glial cells [illegible] are absent. There are considerable numbers of neutrophile leucocytes in the vessels; eosinophile leucocytes are also present.

(2) *Twelfth thoracic segment.*—There is a little infiltration of the arachnoid. The pia is almost completely free. The infiltration of the pia in the anterior fissure is confined to its dorsal extremity. There is marked engorgement. Several vessels in the white and grey matter show adventitial infiltration. There is diffuse infiltration throughout the grey matter on the left side; on the right it is confined to the ventro-lateral region of the anterior horn and a small area in the posterior horn. The nerve cells in the left anterior horn are represented by hyaline bodies, in the left posterior horn they show central tigrolysis. In the right anterior horn a few within the area of infiltration are shrivelled and degernerate; others in the margin of the infiltration are of good shape and show sharply defined Nissl's granules. Some cells which are not implicated in the infiltration show severe degeneration. The cells of the different infiltrations are very similar to those in the lumbar segment. There is very little neuronophagia, and neutrophile leucocytes are not present round the nerve cells.

(3) *The sixth cervical segment.*—There is a little infiltration in the sheath of some vessels in the dura. There is marked infiltration within the neural sheath and round some of the vessels of the left posterior root as it crosses the arachnoid. The pial infiltration is almost confined to the dorsal portion of the expansion within the anterior fissure. The vessels are greatly engorged, and there are some small hæmorrhages. There is infiltration of the sheaths of almost all the vessels which cross the white matter and of vessels in the anterior and posterior horns. There is much diffuse infiltration of both anterior horns, the right posterior horn, and the base of the left posterior horn. There is an area of œdematous rarefaction near the centre of the left anterior horn. [illegible] smaller than in the lumbar segment. [illegible] side. In the left anterior horn the [illegible] the exception of a few which are completely necrosed; in the right anterior horn there are many more nerve cells, but they show varying degrees of shrinkage and degeneration. There is considerable neuronophagia on this side.

The infiltration of the sheaths is very similar to that of the lumbar segment. Several of the hyalines are phagocytic; one contains a neutrophile leucocyte in which granules are still present. In the diffuse infiltration more neutrophile leucocytes are recognisable, but they are very degenerate. In the cellular aggregations and amongst the neuronophages a few degenerate neutrophile leucocytes can also be identified.

In the infiltration of the left posterior root neutrophile leucocytes greatly preponderate. Within the vessels there are some eosinophile and considerable numbers of neutrophile leucocytes.

(4) In additional sections adventitial and diffuse infiltration were found in the *medulla, pons, basal ganglia,* and *cerebral cortex.*

A piece of the lumbar cord was emulsified in saline and injected into a Macacus monkey on Oct. 26th, 1912. Six days later the monkey was seen to be less lively than usual, and on examination was found to have considerable weakness of both arms and legs. The animal showed a great disinclination to move from one spot to another, or to jump. The general weakness gradually increased, and the animal was killed by coal gas three days after the onset of symptoms.

Strain B, Passage I.—Female Macacus; weight 3 lb. 9½ oz. No. 7.

Summary of [illegible] —"*Poisoning by coal gas. Acute polioencephali* [illegible] *wound. Helminthiasis.*"

Macroscopic [illegible] *nervous system.*—There was a shaven area over the left eyebrow, and in this was a scar, measuring 8 mm. long, and lying 1 cm. behind and 3 mm. to the left of the nasion. Beneath this there were some adhesions between the scalp and pericranium. A probe could be thrust through a small hole in the calvaria, 1 cm. behind and 1·2 cm. to the left of the nasion. Beneath the hole in the calvaria there was a small perforation of the dura. The dura was tense; its inner surface was smooth and pink. The superior longitudinal and other venous sinuses contained a little fluid blood. The surface of the hemispheres was smooth. The sulci were well marked. The vessels of the leptomeninges were cherry-red. There was a slight adhesion of the dura to the left frontal lobe at the site of the perforation, and beneath this was a yellow spot on the cortex, 1 mm. in diameter. The posterior roots of the first thoracic segment were ligatured before exposure of the whole cord.

The following were the appearances on section. The cortex in the centre of the right hemisphere was pale yellow and the medulla pure white. After fixation in formalin a small red, wedge-shaped area was seen below the yellow spot on the left frontal pole at the site of inoculation. In the mid-brain and pons, posterior to the fifth nerve, the white matter was white and the grey matter grey, and there was no visible injection. Between the second and third cervical segments the grey matter was pink, and there was a bright red point in the base of the left posterior horn. Between the fourth and fifth segments there was a fine, bright red line at the base of the posterior horn. Between the sixth and seventh segments the grey matter was pink and there were visible vessels. Between the eighth cervical and first thoracic segments the grey matter was of an even pink. At the sixth and eighth thoracic segments the grey matter was pink, and minute vessels were visible. The cut surface of the first lumbar segment bulged and was somewhat soft; the grey matter was pale pink. In the third lumbar there were

all spot suggesting
fifth lumbar seg
nerous vessels were
of the sacral cord
was pink

Portions from the right hemisphere, medulla, and from the cervical, thoracic, and lumbar cord were placed in 33 per cent glycerine for inoculation

first sections, taken from the cord for
o diagnosis, showed no infiltration
in 4 per cent saline formalin, was

of the central convolution This wound contains in its centre red corpuscles, a considerable number of neutrophile leucocytes, numerous

Transmission in series —It was found possible to transmit both the strains in series, and to date (Dec 20th, 1912) both have reached their third passage through the monkey In every instance a microscopic examination of the brain and spinal cord showed the lesions characteristic of acute anterior poliomyelitis The symptoms induced and pathological findings will be detailed in a future communication

Discussion —The histological changes in the central nervous system of the two patients, Cases 3 and 4, from whom the disease was successfully transmitted, do not differ essentially from other acute cases obtained this year, from the single fatal case of 1911, and from Dr Head's sporadic case of 1910 Further, they are essentially similar to those described by numerous observers in sporadic and epidemic cases, both in England and abroad The character of the illness of the monkeys, and the changes found in them on post-mortem examination, show conclusively that they were suffering from a disease similar to that of the children from whom they were infected There are certain minor differences in the histology—for instance, the greater prominence of neuronophagia in the case of the monkeys—but the differences are of degree rather than of kind It is of interest to note that the virus from Case 4 produced an almost pure polioencephalitis in its first passage in the monkey, whilst in later passages the most pronounced changes were in the cord

The failure to obtain a positive inoculation with material from Case 2 is explicable on the grounds that the patient had recovered from his attack of infantile paralysis, as is shown by the histological examination Death resulted from an intercurrent disease—diphtheria

In Case 1 the failure is more difficult to explain. The problem why material from one case of acute poliomyelitis and not from another should produce the disease in monkeys is at present occupying the attention of numerous pathologists Flexner in his Huxley lecture states that about one half of the cords of cases submitted for examination can be successfully inoculated into monkeys Roemer obtained successful inoculation in three out of five attempts, whilst Levaditi obtained three out of four

When the histological changes in Cases 1, 3, and 4 are compared, it is found that in Cases 3 and 4 the diffuse infiltration and the destruction of the cord are greater, pyknotic nuclear remnants, phagocytes, and fat-granule cells are more numerous, and neutrophile leucocytes are far fewer Comparison of the histological changes in different cases, and especially in different portions of the cord in individual cases, shows that the emigration of neutrophile leucocytes is a relatively early phenomenon, and precedes signs of profound destruction of the nervous tissue The emigrated leucocytes rapidly degenerate and disintegrate, whilst polyblasts become more numerous The fragments of

the chief sources
xtent engulfed by
ous tissue becomes
marked more polyblasts assume the form of fat-granule cells Probably, therefore, the histological peculiarities of Case 1, when compared with Cases 3 and 4, merely indicate that in Case 1 the changes in the tissue were in an earlier stage

In such a case, in which the early stage of the disease is not only indicated by the character of the histological changes but by the death of the patient within 48 hours of the onset of symptoms, the presumption is that active virus was present in the cord It has been suggested that the distribution of the virus in the nervous system may be irregular, inasmuch, therefore, as a portion of the cervical cord was alone used for inoculation the virus might thus have been missed This, however, is extremely unlikely, because the section which was taken from the portion sent for inoculation showed marked histological changes, and similar changes were present in all other sections from the cervical region Again, the failure of inoculation might be attributed to deterioration of the virus *as the result of the* cord having been kept for 11 days in the ice chest It has, however, been shown that a cord kept under similar

any weeks
the monkeys may
cord was inoculated
into three monkeys (Macacus rhesus) From observations on the experimental disease in these monkeys it is known that the use of such a number is sufficient to exclude any individual insusceptibility Again, the fact that several months later one of the three monkeys was successfully inoculated with the disease conclusively proves that at least one susceptible animal was used It is, therefore, most likely that the cause is to be found in a variation of the pathogenicity of the virus itself

In the neighbourhood of the London Hospital, as previously stated, the disease has been on the increase in late years Not only have the cases admitted to the hospital increased in number, but the records of the Pathological Institute show that there has been an increase in mortality Between 1907 and 1911 *no* case of uncomplicated poliomyelitis came *to* post-mortem examination, in 1911 three cases were examined, but in one only was the death (September) directly due to the disease, in 1912 four cases were examined, and in all

by the London Hospital

A mild epidemic appears, therefore *to* have gradually
developed from sporadic c
is not only shown by the
the cases, but by the feeb

transmitted to monkeys. The virus, unlike that which has been raised from epidemics in America and on the continent, has not yet produced a fatal disease in the monkeys.

Cases 3 and 4, therefore, occurred in a mild epidemic, whilst Case 1 was sporadic. This may be the explanation of the variation in the pathogenicity of the virus. The work of other investigators has shown that it is extremely difficult to transmit the virus from sporadic cases, whilst in epidemics transmission is successful in the great majority of instances.

We suggest, therefore, that in sporadic cases the virus is feeble, and the occurrence of the disease is due to a hypersusceptibility of the individual attacked, whilst an epidemic only results when the virus has become exalted either by a series of passages through susceptible individuals or from some other cause unknown. It seems probable that the virus has been gradually exalted during the last three years in the neighbourhood of the London Hospital, until a mild epidemic occurred in 1912. It will, therefore, be of great interest to note whether the pathogenicity increases in 1913.

We are greatly indebted to Dr. Henry Head for allowing us to publish his case, to the members of the medical staff of the London Hospital for permission to make use of the clinical notes on the patients under their care, to Dr. E. G. Fearnsides, medical registrar, for valuable assistance, and to the administrators of the London Hospital Medical College Research Fund for a grant towards the expenses.

December, 1912.

TWO CASES OF PANCREATIC CYST.

By W. F. CHOLMELEY, F.R.C.S. ENG.,

HONORARY SURGEON TO THE GENERAL HOSPITAL, WOLVERHAMPTON.

CASE 1.—The patient, a male, aged 19, came under my care with symptoms of intestinal obstruction. He had absolute constipation and had vomited. The abdomen was not much distended, there was no vomiting or marked tenderness, nor could a "lump" be felt. The attack had come on quite suddenly with acute pain in the epigastrium, and had been followed by vomiting. Enemata and purgatives were tried, but without effect. After four days, during which time every endeavour was made to get an action of the bowels, I decided to explore the abdomen, even though the patient did not look as ill as cases of intestinal obstruction usually do. I looked upon the case of one of enterospasm.

The abdomen was opened in the middle line below the umbilicus, and there appeared to be nothing wrong. There was no excess of fluid, no injection of the peritoneum, nor were the intestines much distended. The wound was closed and the patient taken back to bed. The next day the bowels opened quite naturally. The urine was tested twice before the operation, and no sugar was found. A day or two after the operation the patient began to complain of attacks of colic in the epigastric region. At first nothing abnormal could be felt, but the epigastrium began to swell quickly, and became tender. By the end of 10 days a definite tumour made its appearance in the epigastrium, and caused a good deal of pressure on the transverse colon. During the attacks of colic the bowel could be seen moving over the lower part of the tumour, and the colic disappeared as soon as the contents of the bowel had passed along with a gurgling sound. The urine was again tested and found to contain sugar. I then diagnosed a pancreatic cyst, and decided to open the abdomen and drain.

Sixteen days after the first operation I opened the abdomen in the middle line above the umbilicus, and over the most prominent part of the tumour. The cyst was found to be pushing its way between the stomach and the transverse colon. The general peritoneal cavity was packed off by gauze swabs, and the cyst tapped with a full-sized trocar and cannula. A large amount of thin, yellowish-coloured fluid was drawn off, full of what looked like cholesterin crystals. There did not seem to be any definite cyst wall beyond the thickened peritoneum of the lesser sac. This was sutured to the parietal peritoneum and a large bore rubber tube fixed in the cyst. The wound was sewn up to the tube.

Little need be said about the further progress of the case. Within 24 hours the fluid draining away from the cyst caused intense irritation of the skin, which was with difficulty kept within bounds. The patient made an uninterrupted recovery, the sinus taking three months to heal. The glycosuria disappeared in a fortnight. About the fourth day after the operation there was a sudden rush of bile-stained fluid from the cyst, which flooded the dressings and soaked the bed. For some time after this the discharge contained a good deal of bile. Unfortunately the full notes of this case have been lost, so that the gaps have to be filled in from memory.

CASE 2.—The patient, a lady aged 75, came under my care in December, 1911. The history obtained is as follows. The patient had an attack of acute abdominal pain about the second week in September. This lasted about four hours. There was no vomiting, and the pain was chiefly in the left hypochondrium and right iliac fossa. Shortly after this attack she began to notice that her clothes were feeling tighter round the abdomen, and she suffered from thirst. A second attack of pain occurred at the end of November, lasted much longer, and was accompanied by vomiting, and more or less intestinal obstruction for five days. This was relieved by repeated doses of calomel, and oil enemata given through a long tube. She had had some diarrhœa and what was thought to be indigestion for a few weeks before. The pain was situated in the same place as in the former attack. After this second attack there was increased thirst.

I first saw the patient on Dec. 22nd. She then looked extremely ill, the abdomen was so swollen that she was unable to fasten her clothes properly, the tongue was very dry and coated, and she complained very much of thirst. The patient found it impossible to sit in one position for a long time, and could not sit upright at all on account of the pain it caused, no doubt due to the pressure on the cyst. On the evening of the same day she had an attack of very acute pain in the abdomen, chiefly in the epigastrium. On examination, a swelling was felt occupying the whole of the epigastrium and about the size of a full-term child's head. The tumour was smooth, tense, and elastic, not very tender, and was dull over the upper part, and faintly resonant over the lower. Though the pain was evidently very acute, there was no collapse, and the pulse remained good. The acute pain lasted about three hours, but she was not quite free from all pain until the next morning. The urine was tested and found to contain sugar, 10 gr. to the ounce. There was no polyuria. I looked upon the case as one of pancreatic cyst, but on account of the patient's extreme weakness did not feel justified in advising operation. On Dec. 25th Mr. E. Deanesly very kindly saw her with me, confirmed my diagnosis, and advised no operation. He suggested a slightly restricted diet and codeia ½ gr. twice a day.

The patient gradually improved under this treatment, and though there were at times some colicky pains, she had no acute attack. The amount of sugar slowly decreased, and at the beginning of the third week in January had disappeared. The cyst gradually grew larger, and began to give trouble by pressing on the stomach or colon, I could not be certain which. During the third week in January the restricted diet began to pall and irritate the patient, who became anxious for something to be done to relieve her. As her general condition had greatly improved, and there was no longer any glycosuria, I decided to operate.

On Jan. 21st the patient was anæsthetised by Dr. E. W. Strange, a mixture of chloroform and ether being used, and assisted by Mr. A. H. W. Hunt I opened the abdomen in the middle line above the umbilicus and over the most prominent part of the tumour. The cyst was seen to be pushing its way above the stomach As the slightest attempt to get below the stomach to drain the cyst brought on the most alarming collapse, it was thought best to drain above the stomach, and finish the operation as quickly as possible After carefully tearing through the gastro hepatic omentum I tapped the cyst with a large sized aspirating needle and drew off 3 pints of chocolate coloured fluid When no more fluid would come away, the opening in the cyst was carefully enlarged, until I could introduce my finger A good deal of débris could be felt in the cyst a large quantity of it being fairly firmly adherent to the lower part of the cyst wall Some of it was removed for examination, and looked like a mixture of sloughs and old blood clot The wall of the cyst was ⅛ in thick, and seemed as if it would peel out with ease I did not try to peel it out as the patient s condition would not allow of a long operation and I was well aware of the pitfalls awaiting me should I attempt it The cyst wall was sutured to the abdominal wall, a large rubber tube fixed in and the wound sewn up

The patient stood the operation very well and had very little pain after The discharge very quickly caused intense irritation of the surrounding skin As was expected sugar appeared in the urine immediately after the operation and remained until Feb 1st On Jan 29th there was a sudden rush of a large amount of bile stained fluid mixed with mucus This was repeated about a week later and each time soaked through the dressings and flooded the bed For some time small sloughs and other débris came away when dressing the patient being brought up by syringing with hydrogen peroxide On Feb 19th a large slough 3 inches long and 1 inch broad came away The patient was allowed up in a fortnight No diabetic diet was given after the operation, and the codeia was stopped when the sugar disappeared The further progress of the case was excellent until March 8th when she was seized with an attack of acute bronchitis which nearly proved fatal Glycosuria appeared again when the bronchitis started and did not again disappear The patient was allowed out of bed on May 2nd and went away on July 11th It was unfortunate that in this case the cyst could not be drained below the stomach at its most most dependent part, as it was bound to take very much longer to fill up When the patient left there was still a long sinus present

The fluid in the first case was proved to contain pancreatic secretion but I have not the report by me The reports on the second case I append and were made by the Clinical Research Association —" The fluid is of a dark colour, it is faintly alkaline, has a specific gravity of 1010 and an albumin content of 0 7 per cent There is no evidence of proteid digestion or fat splitting but there is conversion of starch The centrifugalised deposit is considerable in amount, and consists of many blood discs a small number of leucocytes an occasional epithelial cell and much fat débris part of which occurs as neutral fat and in fatty acid crystals The specimen is non purulent in character but a fair number of Gram negative bacilli are seen to be present On culture these are coliform in type "

The report on the piece of débris is —" This material is far too necrosed for a definite opinion to be given We feel morally certain, however, that it is pancreatic tissue There are many areas which suggest fat necrosis and some parts suggest outlines like those of pancreatic acini There are many masses of cells filled with blood pigment and in the centre there is a fibrous nodule containing a duct It is difficult to see why so large a fibrous mass should form round a pancreatic duct but that is clearly the suggestion There is no evidence of malignant growth

The first case was undoubtedly a pseudo cyst the attack simulating intestinal obstruction being caused by the rupture of an old cyst into the closed lesser peritoneal sac I did not drain directly the cyst but the lesser sac The second case I look upon as a true pancreatic cyst There seemed to be a definite cyst wall ⅛ in thick which would have peeled out to some extent at least with great ease—not what would be expected of the peritoneum of the lesser sac

The etiology of the second case I take to be as follows A large retention cyst had formed as the result of chronic pancreatitis The fibrous nodule round a duct seen under the microscope suggests the chronic pancreatitis The attacks of acute pain were caused by hæmorrhages into this cyst, while the attack at the end of November was one of acute pancreatitis most probably hæmorrhagic involving that part of the pancreas to which the cyst was more directly connected There had no doubt been some very acute pancreatic mischief, or how are the sloughs to be explained? I do not think that the acute pain on the evening of Dec 21st was caused by another hæmorrhage, as the cyst was not more tender than it had been and the pulse never failed in the least There was however, every reason for a hæmorrhage at that time as the patient had been a railway journey of 70 miles that day

Both patients at the present time are doing very well, though the second case still has a sinus and a slight amount of glycosuria

Wolverhampton

TWO CASES OF PANCREATIC CYST WITH ACUTE SYMPTOMS

BY CLAUDE FRANKAU, M B LOND F R C S ENG ,

ASSISTANT SURGEON TO ST GEORGE S HOSPITAL.

CYSTS in connexion with the pancreas are not in themselves very uncommon, the onset of acute and urgent symptoms as the first indication of the presence of such cysts is however of sufficient rarity to warrant a note on two such cases which have recently been under my care at St George s Hospital

CASE 1 —The patient a female aged 46 was admitted into St George's Hospital on Sept 24th 1911 and gave the following history For three weeks she had had abdominal pain of a spasmodic character, this at first was not severe, and was mainly referred to the navel, later it became more marked, and for the four days prior to admission had been almost continuous and had shifted to the right hypochondriac region In addition to the increased severity of the pain there had been also almost incessant vomiting of bile stained fluid in small quantities and absolute constipation for five days Her health had previously been excellent; there had been no jaundice The only previous medical history of any importance was that of a somewhat doubtful abdominal injury some 20 years previously

On examination the patient was an extremely well-nourished woman The expression was anxious and she was clearly in pain, at frequent intervals small quantities of bile were vomited The tongue was furred, temperature *100° F* and *pulse 104* *The abdomen showed considerable* general distension but moved well, on palpation an extremely tender rounded swelling could be felt somewhat below and immediately to the right of the navel This was quite localised and fixed, it was dull to percussion, with an area of resonance above and below it The size of the swelling was roughly that of a man s fist The remainder of the abdomen showed no abnormality apart from some general tenderness As enemata produced no result and the symptoms persisted operation was decided upon four hours after admission

Operation — A three inch incision was made over the centre of the swelling through the outer border of the right rectus, on opening the peritoneum a small amount of free fluid escaped, there was no peritonitis The swelling was found to be a tense retroperitoneal cyst presenting below the transverse mesocolon and apparently of pancreatic origin After packing off the intestines with gauze the cyst was incised and 45 oz of dark brown fluid were evacuated At the bottom of the cyst a hard rounded body of the size of a walnut was found and removed, this proved to be composed of layers of dried blood clot A large drainage tube was then sewn into the cyst and the abdominal wall partly closed, a gauze plug was also left in below the tube The fluid from the cyst was deeply blood stained and contained a large amount of albumin the reaction was alkaline Trypsin was present in considerable quantity, as well as a diastatic ferment

The urine passed before the operation contained a trace of albumin and also gave a faint reduction with Fehling s solution, this reduction persisted for about four weeks and then disappeared, the urine at the present time is quite normal

The patient made a good recovery from the operation, and apart from some irregular pyrexia, for which no cause could be found, showed no untoward symptoms. The discharge from the cyst was at first very profuse, as much as five pints being collected in the 24 hours; later the amount diminished to a considerable degree, but the sinus showed no sign of closing. No trypsin could be found after the first three weeks, and the skin around the sinus remained healthy throughout. On Jan. 11th, 1912, she was sent to the Atkinson Morley Convalescent Hospital; the discharge still persisted and at times was blood-stained. On Feb. 20th a considerable amount of hæmorrhage occurred from the sinus, which had a small short tube in it; three days later very severe hæmorrhage occurred, which could not be controlled, and she was accordingly readmitted into hospital.

The patient then showed signs of severe hæmorrhage, with extreme pallor, restlessness, sweating, and a small, rapid, very feeble pulse. It was obvious that an immediate attempt would have to be made to check the bleeding. Accordingly, under intravenous ether anæsthesia, administered by Dr. J. Blumfeld, the cyst was freely exposed and completely marsupialised by means of stout silk ligatures; the shallow cavity was packed with gauze wrung out in 1 per cent. formalin. The bleeding was apparently coming from the granulations covering the surface of the cyst cavity, and not from any large vessel, as had been feared. The patient made a rapid recovery from the effects of the hæmorrhage, and the discharge from the cyst gradually diminished; it has, however, never quite ceased and still persists to the extent of about half an ounce a day from a tiny sinus. The woman's general health is excellent, and she has been doing her household work for the last nine months.

CASE 2.—The patient, a boy aged 14, was admitted into St. George's Hospital on June 9th, 1912, with the following history. Four weeks previously, as the result of a fall across a gate, he injured his left side, fracturing two ribs; in addition to the fractures some grave intra-abdominal injury was also suspected, as for a time he was profoundly collapsed. No further symptoms developed, however, and in about ten days he appeared to be in good health again. About a fortnight later he began to complain of pain in the left hypochondrium, with nausea and vomiting at times; no local physical signs could at first be found to account for this, but some days later a swelling was detected beneath the ribs on the left side. On the day of admission this swelling, which previously had remained stationary in size, was noted to have become very much larger, and the general symptoms became grave. There had been no previous illness of any note, and the boy's general health had been good.

On examination the boy looked extremely ill; the skin was cold and clammy, the tongue dry and furred; temperature 100° F., pulse 120. The abdomen showed slight general distension, with impaired movements and some bulging in the left hypochondrium To palpation the parietes were resistant, and pain was complained of, especially over the bulging area, where a rounded tumour could be felt. This tumour was fixed and quite dull to percussion all over; the dulness also extended upwards as high as the sixth rib in the mid-clavicular line; the tumour did not fill the loin and could not be obtained bimanually; there was no movement on respiration. A small amount of free fluid could be detected in the right flank. There were no abnormal signs in the chest and the apex beat was not displaced upwards. An examination of the urine made before the operation showed no abnormality, except what was then thought to be a very doubtful faint reduction of Fehling's solution.

Operation.—A 4-inch incision was made through the upper part of the left rectus. On opening the peritoneum a quantity of thin, blood-stained fluid escaped; the visceral peritoneum was found to be deeply injected, and the intestines were markedly distended. An examination of the great omentum revealed numerous small spots of fat necrosis; a small piece of omentum removed for microscopical examination confirmed this diagnosis. On further investigation the swelling was found to be a tense retroperitoneal cyst which was presenting above the transverse mesocolon, and over the surface of which the stomach was tightly stretched; the transverse colon was displaced downwards into the lower part of the abdomen. As it did not seem possible to approach the cyst from above, the transverse colon was drawn upwards over the swelling and the mesocolon incised, exposing the lesser sac and the under surface of the cyst, which partly obliterated this cavity, but was situated behind it. On incising this cyst three pints of blood-stained fluid escaped; a large drainage-tube was then sewn into the opening, and the abdominal incision was closed. The fluid from the cyst was practically identical with that found in Case 1, and contained a large amount of trypsin. Further examination of the urine showed a definite trace of dextrose estimated at 0·25 per cent.; this disappeared after the eighteenth day, and has never been found since in repeated examinations.

A large amount of fluid drained away for the first few days, the discharge then diminished, and the wound had entirely healed in three weeks. There was a considerable amount of distension, with flatulence and hiccough for the first four days; this was overcome by the use of turpentine enemata and eserine sulphate given hypodermically in 1/100th gr. doses. Apart from the distension no untoward symptoms developed, and the boy at the present time is in good health.

Remarks.—In the majority of cases cysts of the pancreas, whether arising spontaneously or as the result of an injury, are not associated with acute symptoms, but are somewhat insidious in their course. The interest of these two cases lies mainly in the acute nature of the symptoms, and the difficulty of making a diagnosis before operation.

In the first case a tentative diagnosis of appendicitis, with abscess and partial obstruction from adhesions, was made. The difficulty in this case was increased by the obesity of the patient, which is not common in pancreatic disease, and apart from the somewhat high position of the swelling, the symptoms and signs markedly resembled the above condition. At the operation no definite pathological condition apart from the cyst could be found, and presumably the pain and obstructive symptoms were due to pressure produced by the rapid enlargement of the cyst.

In the second case the history of comparatively recent injury of a severe nature made several diagnoses possible. From the position of the swelling extending high up under the costal margin, and from the presence of free fluid in the peritoneal cavity with signs of a diffuse peritonitis, a partial rupture of the spleen, with recurrence of the hæmorrhage and leakage into the general peritoneal cavity from this cause, was suspected. The operation showed that the acute symptoms and the free fluid were due to leakage from the cyst producing a diffuse peritonitis with fat necrosis similar to that found in cases of acute pancreatitis. Under the circumstances it is remarkable that the peritoneal symptoms disappeared so rapidly after operation.

The examination of the urine, in each case performed before the operation, revealed a faint reduction of Fehling's solution, but this reduction was so slight that at the time it was ignored; later investigations showed that the reduction was due to dextrose, as proved by fermentation tests. The importance of the presence of a reducing body was not apparent till operation, and if it had been realised it is possible that a more satisfactory diagnosis might have been made.

The pathology of the cysts necessarily cannot be absolutely determined; in all probability they were in both cases examples of the prepancreatic type of cyst—i.e., they were situated behind the posterior parietal peritoneum in front of the pancreas, which formed part of the posterior wall of the cyst. There is no doubt that they were not so-called cysts of the bursa omentalis, since the cavity of the lesser sac was free in each case. The presence and persistence of pancreatic ferments in the cyst fluid afford further proof of an intimate connexion with the gland.

The recent injury in the second case was undoubtedly the cause of the condition. In the first case the injury was so remote that it can hardly be regarded as the causative agent; that the cyst had been present for a long period is made probable by the presence within it of the laminated blood clot forming a blood ball.

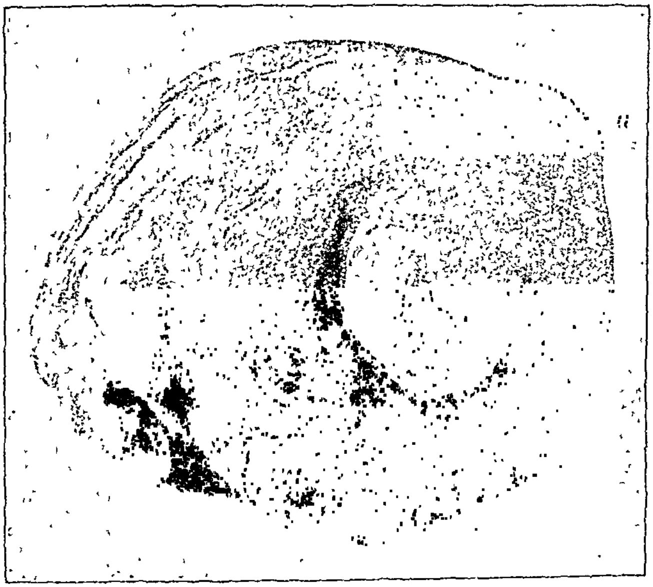
Complete "marsupialisation" of the cyst was practically impossible in both cases in the first instance; it was successfully performed at the second operation in the first case, and it is certain that if it could have been performed at the first operation the severe hæmorrhage which occurred might have been avoided.

South-street, Park-lane, W.

LARGE RENAL CALCULUS ASSOCIATED WITH SARCOMA OF THE KIDNEY.

BY DOUGLAS DREW, B.S. LOND., F.R.C.S. ENG.,
SURGEON TO THE HOSPITAL FOR WOMEN, SOHO.

THE following is a brief account of the patient's illness. A married woman, aged 46, was admitted to the Hospital for Women, Soho, on July 19th, 1912, in a very emaciated and feeble state; she stated that she had been gradually getting thinner and weaker for six months, and had suffered much with pain in the right side, but had continued to work until a fortnight before admission. The swelling in the abdomen had been noticed for three months, and on several occasions blood had been passed in the urine. On admission the right side of the abdomen was occupied by a large tumour extending from beneath the ribs down to the pubis; the anterior edge extended rather beyond the middle line; it was uniformly hard, smooth, and very tender. The total quantity of urine varied between 28 oz. and 40 oz., and usually contained a small quantity of pus and a little blood. The temperature varied between 99° and 102·6° F. No X ray examination was made, as the patient was too ill to be moved out of bed for the purpose.



Large phosphatic renal calculus, weighing 14¾ oz. when wet, and 11 oz. when dry. (Natural size.) *a*, Ureteric end.

On July 31st the tumour was explored through the usual oblique incision in the loin. At the posterior part of the wound it was found that the tissues were inflamed and very adherent to the kidney, while at the anterior part there was a soft mass of deep reddish-purple colour suggestive of a growth. A trocar was inserted into the organ, and a quantity of creamy pus evacuated. The stone was found tightly wedged into the pelvis of the kidney, and considerable difficulty was experienced in delivering it through the wound owing to its size. After its removal several handfuls of what appeared to be broken-down blood clot were removed from the pelvis of the kidney. I have no doubt, in the light of subsequent events, that this material was in reality necrotic growth filling the pelvis. The patient's condition was so unfavourable that a primary nephrectomy was out of the question, so a gauze plug was inserted to check some free oozing, together with a drainage-tube, and the patient was returned to bed. For a few days after the operation the patient appeared to be progressing satisfactorily, the temperature fell to normal, and she expressed herself as feeling much better; but by August 9th it was obvious that she was failing, and she died on the 15th.

The calculus weighed 14¾ oz. in the wet state; it was of a rounded shape and measured 10 in. in one circumference and 9½ in. in another. On one side there were five truncated processes where it fitted into the calyces, and on the opposite side was a nipple-shaped process corresponding to the ureter (see figure). It was of soft phosphatic material and thickly coated with soft débris; it closely resembled in size and shape an average-sized clenched fist.

Necropsy.—The whole of the right half of the abdomen was invaded by semi-solid necrotic material, which was shut off from the abdominal cavity by peritoneal adhesions. The area of invasion extended from the under surface of the liver to Poupart's ligament; the cæcum and ascending colon were pushed over towards the middle line. On clearing away this breaking-down tissue the remains of a large disorganised kidney were found, which was so firmly fixed to the surrounding structures that it could only be separated from the vertebræ and iliac fossa by using the knife. The other abdominal organs were normal, and there were no secondary growths; the left kidney was about twice the usual size, but otherwise appeared normal. The remains of the kidney showed a dense fibrous wall which on section was composed of fibrous tissue with yellow areas; the outline of the calyces was visible, and the pelvis was greatly enlarged and the wall thick and fibrous.

I am much indebted to my friend, Dr. T. G. Stevens, for examining the specimen and giving me the following report of the microscopic structure of the wall of the kidney and of the soft necrotic tissue which was so abundant: "Section from the dark brown, soft material. This is too degenerate to yield any definite result, but it is evidently cellular and composed of necrosing growth. The other section, made from the dense fibrous tissue with yellow areas and soft white growth, is better preserved, and shows that the growth in the main has the characters of a large spindle sarcoma; the yellow areas are patches of hæmorrhagic and necrotic growth. Remnants of renal tissue with tubules and glomeruli are found in the dense fibrous wall."

Remarks.—Renal calculi of such large dimensions are extremely uncommon, as the condition usually causes a pyonephrosis long before such a size is reached. Marmaduke Sheild has recorded a case in THE LANCET* which weighed 1 lb. 9 oz. in the wet state, and 1 lb. ½ oz. when dry; and he pointed out how slight the symptoms had been, although the calculus must have been present for a long time. It was the same in the case now recorded; the patient actually continued at her work until a fortnight before admission to the hospital. I have recently seen an X ray photograph of a remarkable case, which was under the care of Hurry Fenwick, of two stones in the same kidney which weighed after removal by operation 1 lb. 12 oz. when dry. In the case now recorded the stone weighed 11 oz. when dry.

The onset of the sarcoma probably dated from shortly before the appearance of the tumour. I have been unable to find any record of a sarcoma arising in a kidney so affected; it is not unreasonable to suppose that the irritation of the stone in some way brought on the growth.

Wimpole-street, W.

NOTE ON A CASE OF BENCE-JONES PROTEINURIA.

BY JOHN HENDERSON, M.D., CH.B. GLASG., F.R.F.P.S. GLASG.,

ASSISTANT PHYSICIAN, ROYAL INFIRMARY, GLASGOW; ASSISTANT TO MUIRHEAD PROFESSOR OF MEDICINE, GLASGOW UNIVERSITY.

THIS note refers to a case of which I published the clinical details some time ago in THE LANCET.[1] The detailed laboratory investigation of the urine took up considerable time, and thereafter there was unavoidable delay in the publication of the laboratory findings,[2] hence the somewhat belated nature of this communication.

It may be as well to recall the main points of the case. Clinically the striking features were the anæmia, cachexia, and wasting, with, in addition, an unusual urinary condition. The diagnosis was doubtful. The presence of malignant disease was at first suspected, but careful and repeated examination of the patient failed to detect any evidence of it. There was, further, no evidence of disease of the bones. The blood picture was that of a fairly severe secondary anæmia. The case was regarded as one of chronic nephritis of some standing, and probably of the "diffuse" variety, accompanied by a considerable degree of anæmia. The patient, unfortunately, decided to return to his own home in the country, where he died, and no post-mortem examination was obtainable. For the purpose of further urinary investigations, however, several litres of his urine were obtained and preserved in presence of chloroform and thymol.

The urinary condition was shortly as follows. In all the specimens examined the colour was pale amber, and the reaction distinctly acid. The specific gravity averaged about 1015. The daily excretion of urine varied between 1500 and 2000 c.c. The average acidity, as estimated by the *Folin* method = 28 c.c. N/10 NaOH per 100 c.c. Total protein, as estimated by Esbach's method, excreted in 24 hours varied between 15 and 20 grm. When the urine was subjected to the ordinary heat test for albumin an abundant white and rather curdy precipitate was at once obtained well below boiling point. This did not dissolve when boiling point was reached, though there was a partial solution. It, however, completely dissolved on the addition of a drop of 10 per cent. acetic acid. On contact with nitric acid in the cold a copious white precipitate was obtained, which disappeared on warming and reappeared on cooling.

It was at once apparent from these tests that one had to deal with a protein other than ordinary albumin and globulin. In an ordinary albuminous urine the coagulation point may be placed somewhere about 70° C., and the coagulum shows no tendency to disappear on raising the temperature to boiling point. In the present case coagulation began in the urine at 52·5° C., and was complete at 58° C. On raising the temperature it apparently partially returned to solution.

Positive results were obtained with all the ordinary tests for protein: biuret (marked), Liebermann (marked), Millon and tryptophane reactions. Molisch's reaction was very doubtful. The usual blackening was obtained on boiling the urine with lead acetate in alkaline solution.

The protein was precipitated by all the ordinary reagents which precipitate proteins. It was fully precipitated on half saturation with ammonium sulphate, but gave only a slight haze when half saturated with sodium or magnesium sulphate. With alcohol its reaction was unusual, as the usual precipitate in the cold readily dissolved on warming, to reappear on cooling. For further investigation a large quantity of urine was precipitated by means of half saturation with ammonium sulphate and filtered. The precipitate was dialysed against running water, and the products obtained behaved quite as in the original urine. The precipitate was dialysed for a further nine days till free from salt, and it again showed the same properties. The dried substance was obtained in three different ways, viz.:—

1. From the dialysed ammonium sulphate precipitate, by precipitation with alcohol, filtering, then drying. The material was powdered, and on combustion gave a mere trace of ash. It was sparingly soluble in either cold or hot water, but rather more soluble on grinding it up with 1 per cent. sodium chloride solution. It was more readily soluble in acid solutions.

2. From the heat precipitate. This precipitate browned in the air, becoming quite a deep brown in 12 hours. It was dried in vacuo over sulphuric acid. It was not readily soluble in water and dilute sodium chloride solution, though much more soluble in mineral acids. Both this and the preceding preparation slowly dissolved in the cold in 2 per cent. caustic soda or potash. Both dried substances were insoluble in either cold or hot alcohol in all concentrations. Their coagulation point in aqueous solutions was found to be about 56° C.

3. From the dialysed material by evaporation to small bulk in vacuo at 40° C., then drying over sulphuric acid. This form was much more soluble in cold distilled water. Its coagulation point in aqueous solution was 58° C., though slight hazing was observed at 55° C. In other respects it resembled the previous dried substances.

Further investigations were suggested by an extremely interesting paper by Hopkins and Savory[3] on the Bence-Jones protein. They dealt with its relations to variations in reaction and of the salt concentration of the fluid in which it was dissolved. They showed that the characteristic solubility at 100° C. of the heat-coagulated protein was due largely to the influence of electrolytes in solution. This solution was in all probability brought about by the formation of a molecular compound betwwen protein and salt, a compound which was more stable at temperatures near 100° C. than at lower temperatures. They also showed that the solvent power of a salt in neutral solution rose with increase in valency in either its acid or basic constituent, and, further, that with the increase in valency in the acid or basic constituent of a salt the solvent capacity showed also a greater relative increase than does the aggregative (coagulative) power.

Extensive investigation along these lines with the substance obtained in the present case revealed the fact that it behaved in a very similar fashion to that described by Hopkins and Savory. Owing to the scantiness of the available material, however, it was found to be impossible to test all the salts used by these workers. The influence of the three potassium phosphates was tested in the hope that the results might prove of additional value, as the variation in urinary acidity is usually ascribed to variations in the mono- and di-acid phosphates, though Folin denies that these phosphates act in this way. It was further hoped that it might afford some explanation of the variations obtained by different workers in the reactions of the Bence-Jones protein, or allied bodies, in the urine. Very marked variations, however, were obtained, and from these points of view the results were disappointing.

[3] Hopkins and Savory; Journal of Physiology, Cambridge, 1911, vol. xlii., p. 189.

When I published the clinical history of this case, and the urinary investigations carried out, the conclusion had then been arrived at that the substance present in the urine was [illegible] tein, but one allied to it, as, [illegible] blance, it exhibited certain [illegible] protein hitherto described. Since the publication of the work of Hopkins and Savory on this subject, and the confirmatory tests applied in the present case, this protein is now regarded as identical with the substance investigated by these writers. The slight differences found may almost certainly be ascribed to differences in the physical character of the solutions. I now, therefore, place this case on record as one of Bence-Jones proteinuria.

I have again to thank Professor D. Noël Paton and Dr. E. P. Cathcart, Glasgow University, for the facilities afforded for this investigation and for their guidance and help throughout.

Glasgow.

PTOMAINE-PRODUCING BACTERIA IN THE HUMAN INTESTINAL FLORA.

BY D. M. BERTRAND, M.D., Sc.L. PARIS;

AND

A. BERTHELOT, M.D., Sc.L. PARIS.

(From the Metchnikoff Laboratory in the Pasteur Institute, Paris.)

TWO years ago Dr. Ackermann[1] succeeded in obtaining from histidine by putrefaction a base which has been identified with β-imidazolethylamine prepared at first synthetically by Windauss and Vogt.[2] Since then G. Barger and H. Dale[3] in England, and Kutscher[4] in Germany discovered this amine in ergot, where it is one of the most active principles. The physiological action of β-imidazolethylamine has been fully studied by H. Dale and P. Laidlaw[5] in rodents and carnivora; they noted that a dose of 0·5 mgm injected in the external saphenous vein of a large guinea-pig (about 900 grm.) caused death quickly with symptoms very similar to those obtained in anaphylactic shock. They killed a medium-sized rabbit by injection of 4 mgm. in the ear vein, with the same symptoms. With subcutaneous injections of larger doses the rate of respiration was increased, and then occurred defæcation and micturition, with prostration and some degree of narcosis; gradually recovery took place. In the cat an injection into the long saphenous vein of 2 to 10 mgm. caused vomiting, salivation, and defæcation, and at the same time the respiration became laboured, the animal showing signs of prostration and light narcosis with constriction of the pupils. Same action with bigger doses injected subcutaneously; recovery set in gradually.

We experimented on the same animals with hydrochloride of β-imidazolethylamine prepared by the action on histidine of putrefactive bacteria, for which we are indebted to the kindness of F. Hoffmann-La Roche, and had exactly the same results. We tried then to note the physiological action of this amine in monkeys (Macacus sinicus and Macacus cynomolgus), weighing 1100–1300 grm., by intravenous injection into the posterior saphenous vein.[6] The effects obtained with these monkeys were very similar to those obtained with the carnivora—that is, vomiting and diarrhœa, profuse salivation, and a well-marked respiratory impediment. The lethal dose was 65 mgm.—that is, about 50 mgm. per kilo of animal. The monkey showed the ordinary symptoms, more marked; then followed a full paralysis of the posterior limbs, and after a while of the anterior ones; at the same time spasmodic contraction of the diaphragm. The animal was sprawling, the head sank on the table, and it died in 20 minutes. Post mortem the lungs were found distended; the heart stopped in diastole.

Barger and Dale[7] isolated β-imidazolethylamine from intestinal extract, and they thought that this ptomaine in the intestinal mucous membrane could be due to the resorption of the base produced in the intestinal digestion by the action of some kinds of bacteria on histidine set free by enzymic or microbial hydrolysis of proteins. Control of this hypothesis being valuable in man to throw some light on the pathogenesis of different symptoms of so-called auto-intoxication, we tried to isolate from human stools bacteria able to produce β-imidazolethylamine or β-imidazol-α-amino-propionic acid. With the ordinary technique of isolating bacteria it would have been very difficult to get from intestinal flora micro-organisms with such a specificity of biochemical action; but we succeeded rather easily by the general technique to isolate the aminolytic bacteria that we suggested during the last year.[8] In this case we used a selective [illegible] K_2SO_4 0·20 grm., $MgSO_4$ 0·2[illegible] 0·25 grm., $CaCl_2$ 0·02 grm., [illegible] ·50 grm. Using the physiological properties, so characteristic of β-imidazolethylamine, we studied at first the toxic action of the pure cultures on histidine of the different microbes we succeeded in isolating by this way. Injected intravenously into guinea-pigs, all but one of them showed the characteristic symptoms of acute intoxication by the amine, death ensuing in a few minutes.

Though the toxicological examination of these cultures on histidine was rather convincing of the presence of β-imidazolethylamine, we tried to identify the base; for this we added ten volumes of alcohol to the toxic fluid, which produced a precipitate we separated by filtration. The filtrate was evaporated until a dry residue remained, which was dissolved in water, rendered isotonic, and then injected in the vein of a guinea-pig; death ensued with ordinary symptoms. The toxic substance was soluble in alcohol and was probably of the nature of an alkaloid. Not considering this proof sufficient, we tried to extract β-imidazolethylamine. All the culture media on histidine were treated by the process described by Ackermann.[10] At last, a picrate crystallised, melting at 237° C., and the yellow crystals were quite similar to those of the chemically pure amine. This salt was decomposed to give a hydrochloride, soluble in water, which gave an intense reaction with p. diazobenzene sulphonic acid, characteristic reaction of *histidine and closely related* derivatives. The same solution injected in the vein of a guinea-pig caused death in a few minutes with the peculiar symptoms observed with this pure base.[11]

We then carried out a complete study of this micro-organism, which, by its morphology and general cultural characters, is very nearly related to the bacillus of Friedländer and bacillus lactis aerogenes—that is, Gram-negative, capsulated bacillus, with a well-marked action on a great [illegible] group, has no proteolytic action, but a peptolytic one; it does not produce indol nor phenol from tryptophane or tyrosine. But its biochemical action on amino-acids, compared with those of different strains of bacillus of Friedländer and B. lactis aerogenes from the Pasteur Institute collection, or isolated by ourselves, is much more marked; its affinity for organic substances containing nitrogen is so special that it can be separated from them and be called bacillus aminophilus intestinalis. Neither Friedländer bacillus nor B. lactis aerogenes, indeed, sowed in histidine media, were able to produce β-imidazolethylamine, and their aminolytic properties are far less great. Probably it may be possible to obtain by subcultures in appropriate media organisms having this aminophilic character peculiar to this strain.

When this microbe is grown in a nutrient medium containing per litre of water PO_4HK_2 2 grm., $MgSO_4$ 1 grm., and minute quantities of $CaCl_2$ it grows perfectly well, when nitrogen is provided by KNO_3, $(NH_4)^2 SO_4$, NH_4NO_3, or succinate of ammonium. It is able also to get carbon and nitrogen necessary for its life from glycocolle, cystin, tyrosine, tryptophane, alanine, leucine, histidine, glutamic acid, aspartic acid, and phenylalanine. Many other substances than amino-acids are destroyed by this B. aminophilus intestinalis, and so we remarked that all the following bodies may provide it with nitrogen and carbon or nitrogen only when carbon is furnished by glucose: oxamide, urea, urethane, guanidine, creatine, asparagine, glucosamine—piperidine, collidine—allantoine, alloxane, caffeine, morphine, quinine, pilocarpine, hordenine—ethylenediamine, tetramethyl enediamine, p. oxyphenylethylamine, imidazolethylamine—amygdaline—glycyltyrosine, pentaglycine, luceylglycine. As it can split off carbon dioxide from histidine to give β-imidazolethylamine, we studied carefully its action on tyrosine and tryptophane, from which amino-acids it produces p. oxyphenylethylamine and indolethylamine by the same process.

We have seen, then, that this B. aminophilus intestinalis gives β-imidazolethylamine from histidine when it gets its nitrogen from peptone or a mixture of mono and diamino-acids obtained by hydrolysis of casein, but it is quite impossible to find a minute quantity of this amine when nitrogen is provided by a mineral salt of ammonium. When the nutrient medium is composed of histidine and the ordinary mineral salts without any nitrate, it is impossible to find imidazolethylamine in the cultures, but from these media we were able to obtain imidazolpropionic acid. In peptonised culture media with histidine the microbe produces β-imidazolethylamine, which does not disappear if it is left for a week or more in the 37° incubator; the ptomaine is destroyed when it is the sole substance in the medium able to provide the micro-organism with the nitrogen and carbon necessary for its life.[12]

From all these facts we may conclude that this B. aminophilus intestinalis has well-marked saccharolytic and aminolytic properties. Varying the different nutrient substances with the exception of the amino-acid, the micro-organism may remove the carboxyle group; when this amino-acid is the only substance containing nitrogen and carbon, it is able to show both properties at the same time. We have seen, indeed, that it can get its nitrogen and carbon from various organic molecules. As this micro-organism splits off carbon dioxide very easily from amino-acids in various conditions of media, it seems possible then, to try to supplement the few ideas we have at present on the production of ptomaines in the intestinal tract and to study their acute and chronic action in the human organism.

We succeeded in obtaining from human fæces two other bacteria, one of them rather different from this B. aminophilus intestinalis formerly studied, which micro-organisms can produce imidazolethylamine by the same process. It was, indeed, very probable that this B. aminophilus was not the only one in the intestinal flora able to produce such an action. These micro-organisms have only been isolated from patients suffering from chronic auto-intoxication with some intercurrent intestinal disorder.

The point particularly interesting is that it has always been impossible to get a growth from fæces of people enjoying very good health, exactly as happened in the cases where we isolated formerly "tyrosinolytic" bacteria.[13] We may conclude that by the very simple technique we proposed more than a year ago we have been able to isolate from the human intestinal tract micro-organisms capable of producing a very active base—namely, β-imidazolethylamine—from histidine; further, its isolation does not require more than three days, and frequently we can obtain a pure culture in less than 48 hours.

British Red Cross Society.—The annual meeting of the County of London branch of this society will be held at Grosvenor House, Upper Grosvenor-street, W. (by permission of the Duke of Westminster), on Friday next, Feb. 28th. Viscount Esher will take the chair at 4 o'clock.

THE THERAPEUTIC ACTION OF SPLENIC EXTRACT

AND ITS APPLICATION IN THE TREATMENT OF TUBERCULOSIS.

By HENRY R. HARROWER, M.D.,

LATE PROFESSOR OF CLINICAL DIAGNOSIS, MEDICAL DEPARTMENT, LOYOLA UNIVERSITY, CHICAGO, U.S.A.

The original work of Dr. Charles Bayle,[2] of Cannes, France, has stimulated my interest in the use of spleen substance or extract in tuberculosis, and while the literature on this subject is still very meagre, a limited personal experience, coupled with that of several correspondents in the United States, France, Italy, and Russia, convinces me of its importance. Since tuberculosis is essentially a wasting disease, a vital part of its treatment is the attempt to increase the nourishment of the body, thereby enhancing its resisting powers. Hitherto this has been attempted by careful attention to diet and, in many cases, a *régime* which has come to be termed "hyperalimentation." I certainly believe that fully as much harm as good has been accomplished by the extremes of feeding that have resulted. Toxæmia due to putrefying proteid has frequently undone much of the good that the other treatment may have accomplished; and while in some cases benefit has been derived from the increased food ingested, many others have suffered inconvenience and disadvantage from the resulting indigestion.

For nearly nine years Bayle has used spleen preparations in tuberculosis, and in his latest communication,[6] which was read before the International Congress of Tuberculosis at Rome, April, 1912, he concludes:—

> I feel authorised by my results to call splenic opotherapy a specific treatment for tuberculosis. It is specific from the therapeutic viewpoint because it modifies the soil, rendering it less suitable as a medium for the culture of the bacillus of Koch. It is specific from the practical viewpoint because it manifests all the function and rapidity of action of a specific medication. Employed in convalescents it prevents tuberculosis by increasing the mineral content of the tissue *(en reminéralisant le terrain)*. Employed in confirmed cases of tuberculosis it cures them.

In an earlier communication[5] Bayle refers to "150 cases *treated by me in which I have noticed 146 showing the* unquestionable and rapid effects of the treatment. Among those which I have been able to follow a sufficient length of time to acquire some conviction I note 75 per cent. of cures, some of which were in a very advanced stage and regarding whom I had no hope to begin with."

In no disease have so many and such varied remedies been recommended as in tuberculosis, and the mere number alone is evidence of their unsatisfactory results. Time and again our hopes have been raised, to be as frequently rudely dashed to the ground. One therefore accepts with considerable reserve such enthusiastic statements, no matter how thoroughly they may be backed up by clinical results. While many have considered Bayle's experiences as "too good to be true," there is no doubt that a more general trial of spleen preparations in tuberculosis will be both interesting and profitable.

Unfortunately, the most recent books on the internal secretions—notably the exhaustive monograph by Biedl[10]—make no reference whatever to the internal secretions of the spleen; and Swale Vincent[41] gives this subject only four lines in his new book. In fact, opinions on the subject have been so difficult to obtain that the results of my researches in the literature have been collated here. Possibly these eminent writers have omitted to refer to the spleen because it is not really a glandular organ, and is not presumed to have any other than its well-known hæmopoietic function. Other investigators have expressed their doubt as to the hormone-producing powers of the spleen. Professor Osborne,[34] of Yale University, says:—

> From a histologic standpoint and from the standpoint of what is known of the physiolog[illegible] fact than man and animals can live after t[illegible]. It seems doubtful if this organ furnishes [illegible].
>
> When the spleen is removed, the lymph glands do its work. After such removal there is an increase of the lymphocytes in the blood and a decrease of red corpuscles, as well as a reduction of the hæmoglobin, but in a few weeks the blood becomes normal.

Histologically the spleen cannot be included with the glands or ductless glands, as its structure does not consist of epithelial cells

Hutchison, in his Goulstonian lecture,[26] mentions the following functions of the spleen —

[illegible]

Hutchison further emphasises his belief in the limited view of the splenic functions in his excellent little book on physiology, in which he says[27] —

[illegible]

And this in spite of the experiments of Herzen, Bellamy, and a dozen others, reference to which will follow

It is believed by some, however, that the spleen produces certain secretions which, like those of the thyroid adrenal, or pancreas are passed directly into the blood to influence both the producer's own function and that of organs remote from it From the experimental work which has been done one gathers that the above statements of Osborne and Hutchison, together with the presumed opinions of authors already referred to are incorrect

The earliest discovery of the influence of the spleen on the pancreatic function was by Professor Schiff[42] His original ideas however, were faulty, and to his successor A Herzen,[13] professor of physiology at the University of Lausanne, must be given the credit of having definitely settled this question His experiments were most convincing, and proved that the spleen acts as a tryptogene by means of some unknown substance which it proliferates and which is carried by the blood to the pancreas This work has been duplicated by his associate Bellamy, whose experiments at Lausanne corroborated Herzen's ideas of the relations of the spleen and pancreas He concludes that[8] "the inactive zymogen granules present in the cells (of the pancreas) receive from the spleen in the form of an internal secretion the agent with which to elaborate trypsin" The blood carries this product to the pancreas in its solid elements The jejunal mucosa also furnishes a similar tryptic activator, which is produced quite independently of the spleen Bellamy[7] writes further regarding this, "without any reference to the possible and perhaps equally important manner in which the spleen acts in other departments of the animal economy, I propose to consider the spleen in the light of a powerful and indeed essential factor in the pancreatic digestion of proteids , and he follows this up with a convincing and comprehensive review of his work and that of his colleagues at Lausanne

Hedin's experiments[21] demonstrated the presence in the spleen of two proteolytic ferments easily destroyed by heat, the one active in acid media and the other in alkaline Rettger[33] also has injected directly into the circulation of splenectomised dogs an aqueous extract of spleen and has demonstrated a definite rise in the trypsin coming from the pancreas Studies on the relation of the spleen to pancreatic function have been made by numerous other physiologists notably *Pachon and Gachet,*[35] *C inus and Gley,*[12] *Frouin*[31] *Laguesse*[23] and Schäfer[41]

It has been proved that the protective powers of the organism in part are dependent upon the presence in the leucocytes of a certain amount of active trypsin and it is believed that phagocytosis is virtually digestion of the enveloped bacteria by the white blood cells and further, that trypsinogen passed from the pancreas into the blood is activated by the splenic hormone and the active secretions then utilised by the white cells

In 1894–95 Danilewsky and Selensky[19] worked on this study, and as a result of their experiments they announced that the extract of spleen contains a certain definite substance, not destroyed by heat, which when used hypodermically causes a considerable increase in the hæmoglobin index (from 7 to 40 per cent) as well as in red cell count (from 10 to 40 per cent) Bayle[4] himself assumes that the specific action of splenic extract in tuberculosis is due to some hitherto unknown physiologic influence—possibly a colloid producing function, but whether this function is conclusively proved or not, it will be evident from the foregoing and the references which follow that several of the splenic functions are of such a nature as to explain at least a part of the good results secured from the administration of spleen in tuberculosis

The statement of Bellamy, already referred to, that the intestinal mucosa furnishes a tryptic activator is confirmed by Ciaccio,[16] who also states[17] that he has found an enterokinase in the spleen which stimulates the intestines Girolama, experimenting on rabbits and dogs, failed to show that *splenectomy altered in any way the* secretory functions of the pancreas and liver, and it is *well known and frequently emphasised that splenectomy* does not seriously interfere with digestion Bellamy, however, believed that pancreatic digestion is almost completely destroyed following splenectomy, and that digestion is carried out by the stomach and intestines Experiment shows at least that the increased need for food in splenectomised animals and the proof that digestion is not often as perfect with the spleen *hors de combat* or entirely removed, simply emphasises the fundamental which has long been known to physiologists, that quite often the functions of an organ which becomes diseased or is removed are taken up by the others All this simply emphasises that the splenic influence on digestion is supplementary Pugliese[39] has made experiments from which he deduced that the spleen also has an influence upon the composition of bile and Asher[1] in a very interesting paper emphasises his belief that the spleen is in charge of the metabolism of iron

The question of the relation of the spleen to the blood is much better known A [illegible] is an important part of [illegible] entirely essential to it [illegible] leucocytes and its place as an important defensive organ against disease were emphasised by Bezançon[9] in his thesis Goldschneider and Jacob[22] in 1893 reported that extracts of spleen and thymus produced decided leucocytosis and showed that this was evidently not due to the nuclein contained in these extracts for similar experiments with preparations from the thyroid, liver, and kidney, all of which contain relatively large amounts of nuclein, caused no appreciable influence on the white cell count

Carpenter[13] has had considerable clinical experience with the use of splenic extract in typhoid fever, and believes that the good results which he has obtained are due to an influence in restoring the functional activity of the spleen which it is well known is notably disordered in typhoid Its administration "causes a marked increase in leucocytosis and otherwise restores its (the spleen's) functions to normal Carpenter used five grains of splenic extract three times a day in typhoid fever, and states that this was a means of 'rapidly and steadily reducing the temperature without undue diaphoresis' and that it "*ameliorates all the symptoms and restores* the patient to the normal In a more recent article[14] he also advocates splenic extract as a real remedy for malarial infection ' and explains its action in malaria in the same manner as in typhoid and goes as far as to state that it produces the beneficial effects of quinine without its bad effects Incidentally he also advises the use of red bone marrow which seems to activate the splenic extract in those cases which did not promptly respond to splenic extract alone This is in *corroboration of the experiences of others* who have used spleen in malarial cachexia with a resultant reduction in the hypertrophy of the spleen as well as the other symptoms

It is also believed that the spleen exercises an influence on the coagulability of the blood and in some manner tends to prevent hæmorrhage Landau[29] has used splenic preparations with success in various hæmorrhages and reports especially good results in menorrhagia David has also used an extract of spleen in anæmia *clinically confirming* Danilewsky's experimental studies He also found that not only were the blood findings changed but the appetite was increased and there was a corresponding gain in weight and general resistance

Strangely enough spleen preparations have been advocated in Great Britain for the treatment of certain phases of insanity Clark[18] used it in asthenic cases, with good results both on the general and mental condition Confirmation of this is given by Bois and Kerr,[11] *who pointed* out that splenic extract is often useful associated with thyroid extract where indicated

The most recent statements regarding the use of an extract of spleen are those of Carrel, who in his latest paper,[15] advances the startling view, which is backed up by the most extensive experiment, that certain tissue extracts have the power to activate *in vitro* the growth of connective tissue. While he found that the extract of chick embryos was the most active preparation, extracts of adult spleen were almost as active, while kidney and heart extracts were much less active, and extracts of connective tissue or blood cells were almost without influence. Carrel, in his summary, intimates that these discoveries "may be indirectly useful by leading to the discovery of some of the factors determining the growth of tissues and of the unknown laws of cell dynamics, and may ultimately throw light on the mechanism of the cicatrisation of wounds."

More recently van Stockum[43] has been experimenting with an extract of spleen which has previously been exposed to the Roentgen rays. He reports 3000 treatments, which show that the method is harmless, and that it causes an early change for the better in many cases, especially of surgical tuberculosis. Perez[38] believes that good results are obtainable from the administration of an extract of lymph glands, especially in immunising against tuberculosis.

Further reference regarding the influence of the spleen and its hormone may be found, and interested readers are referred to the writings of Patricelli,[37], Liverato,[31] Grimani,[23] Foà,[20] Maggiore,[32] Salomon and Halvron,[40] Lépine and Lyonnet,[30] and Williams.[45]

There can be no reasonable doubt that the spleen has a very important influence upon nutrition, and that splenic extract is a valuable remedy in the treatment of those conditions in which malnutrition is an important factor. The statements preceding, and a study of the literature referred to in the bibliography, cannot but convince the confirmed sceptic that the splenic functions are far more extended and important than those connected with hæmopoiesis.

To sum up, the use of splenic extract has been advised in several diseases, and I believe not only on general theoretical and experimental grounds, but from actual clinical experience, that it is useful in tuberculosis, and that its value is presumably due to certain splenic hormones, on which, in a degree, the following phenomena are dependent:—1. The defences of the blood; leucocytosis, phagocytosis, and, possibly, hæmoglobin formation and iron metabolism. 2. Tryptic digestion, thus directly increasing assimilation and nutrition, permitting an increased intake of food, and indirectly relieving the emunctories from the excessive work common in toxæmia and sub-oxidation. 3. Intestinal digestion and the production of enterokinase. 4. The process of healing, both as regards the prevention of hæmorrhage and the stimulation of rapid connective tissue production. 5. Antagonism to the tubercle bacillus by an influence on its culture medium, due to the production of a certain colloid substance (Bayle) 6. And finally, the function of the spleen itself.

Hornsey, N.

TRAINED NURSES' ANNUITY FUND (FOR DISABLED NURSES).—The annual general meeting of the members of this fund will be held on Friday, Feb. 28th, at 2.30 P.M., at the Caxton Hall, Westminster. H.R.H. the Princess Christian of Schleswig-Holstein (President of the fund) will preside, and the meeting will be addressed by Field-Marshal Lord Methuen and by Sir Francis Champneys. The honorary secretary is Dr. A. Ogier Ward, 73, Cheapside, E.C.

CHICHESTER INFIRMARY.—The personal interest shown by King Edward in the latter years of his life in the Chichester Infirmary is being maintained by the present Sovereign, who has arranged to visit the institution on August 2nd to reopen the infirmary after reconstruction. His Majesty has intimated that in the event of the governors desiring the title of "Royal" to be given to the institution the board of management should apply to the Home Secretary, and at the annual meeting of the governors on Feb. 13th the trustees were empowered to realise and pay into the general account such a sum as shall free that account from debt and provide a working balance, such being necessary before an affirmative reply would be given for Royal patronage. The annual report showed that the income for the year was £700 less than for the preceding year, but as some of the beds were closed owing to building operations, thus causing a reduction in the expenditure, the loss on the year only amounted to £391. During the year the board of governors received the sum of £1153, subscribed by "the personal friends of the late Mr. William James, C.V.O., as a memorial to him," and also a sum of £300 given by Mrs. William James herself for the furnishing of the operating theatre as a lasting tribute to her husband's memory. It was through this lady that King George's intention to reopen the infirmary was made public. Warm appreciation was expressed at the meeting of the work of the honorary medical and surgical staff, and the extent of their labours is shown by the fact that there were no fewer than 634 in-patients and 3019 out-patients during the year. There were 461 major operations.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE OF A CASE OF GONOCOCCAL PYÆMIA.

BY CLAUDE B. TUDEHOPE, M.B., CH.B. EDIN.,
SENIOR HOUSE SURGEON, WEST KENT GENERAL HOSPITAL, MAIDSTONE.

IN a recent publication, "*Gonococcal Infections*," by Major C. E. Pollock, R.A.M.C., and Major L. W. Harrison, R.A.M.C., I see it stated that only a few cases of the above condition have been recorded. The following case must, therefore, be of some interest.

The patient, aged 25, contracted gonorrhœa two years ago while resident abroad. He received no treatment there, and stated that the discharge cleared up entirely in six weeks. On returning to England 18 months later he had a slight recurrence of the urethritis, and then consulted a medical practitioner, under whose treatment it disappeared in a week. Some four weeks after this (he could not state exactly when) he started "night-sweating," felt ill and unable to work, and was losing his appetite and also losing weight. This general illness continued for four weeks, until one night during an attack of coughing and vomiting while retiring to bed, he "felt something drop" in his left leg. In the morning this leg was swollen and painful, and he could not move it. He was found to have a thrombus in his left internal saphenous vein, and was admitted to the West Kent General Hospital.

The patient was then having slight rigors every evening, and his temperature was rising over 99° F. He would have a profuse sweat during the night, and his temperature would gradually fall until in the morning it was 97°. His liver was 1 inch below the costal margin, and was tender on palpation. He also almost immediately started to cough up sputum containing blood and pus, and examination of his right lung base revealed a small pneumonic area with overlying pleurisy. The sputum was examined microscopically, and revealed pus, pneumococci but no tubercle bacilli. On acquainting the patient with his weight he said that he had lost 1 st. 8 lb. during the last three weeks, and he was assuming a hectic appearance. Although his urine appeared normal and there was no visible discharge from the urethra, there was no difficulty in demonstrating the gonococcus. He was then given 50 millions of gonococcal vaccine, and had a slightly higher rise in temperature, but no other symptoms of reaction. During the week following this injection all his symptoms continued, but towards the end were becoming less severe. He was now given a second injection of 100 millions. Within 24 hours of this his temperature became normal and never again rose above 98·4° throughout the treatment. His liver had now receded to the costal margin and was no longer tender; he coughed very little and there was no sputum. He had no more rigors or night-sweats. Nothing abnormal could be found in his chest except some slight dulness over the pneumonic patch above described. His hectic appearance became less marked. At intervals of a week three more injections of vaccine were given—one of 200 millions and then two of 400 millions each. With the last he had a very decided reaction, with rise of temperature, headache, nausea, and vomiting. These all ceased in six hours. After this he was carefully examined and nothing abnormal could be detected in any system. He no longer had any symptoms whatever, and since the beginning of the treatment his weight had increased 1 st. 1½ lb.

It is worthy of note that the injections of vaccine did not at any time bring on his urethral discharge. He never had any arthritis, and if he had any endocarditis it could never be detected, although often looked for. The origin of the internal saphenous thrombus is just as difficult to explain as the puerperal variety, but I suggest a direct spread from thrombosed prostatic veins. I might also mention that from the fact that this patient had had malarial fever this latter had to be carefully excluded, and, of course, signs of pulmonary tuberculosis were frequently sought for before what I believe was the correct diagnosis was come to.

This case was under the care of Dr. J. Aldington Gibb, honorary physician to the hospital, and I am much indebted to him for permission to put it on record.

Note by DR. J. ALDINGTON GIBB.—The main points of interest in this case are: 1. The rarity of the condition. It was only by a process of exclusion that the actual cause could be diagnosed. Having seen many cases of malarial fever, and having been a sufferer myself, I was able to exclude this. As was to be expected, the gonococci were extra-cellular and in fair numbers. 2. The initial gonorrhœal attack was slight and occurred two years ago. 3. With regard to the thrombosed vein I cannot agree with Dr. Tudehope as to its cause. I think it more likely that it was set up by gonococci getting into the blood stream and infecting the walls of the vein. There are three stages in the spread of gonococcal infection: (*a*) urethral infection; (*b*) blood invasion; and (*c*) tissue invasion. In this case all stages were present. 4. The reaction following the last dose of vaccine was in part caused by auto-inoculation, as the patient was sent home the next day, and I believe spent the evening with friends.

Maidstone.

NOTE OF A CASE OF IMPACTED CALCULI IN THE URETHRA PRESENTING UNUSUAL FEATURES.

BY T. C. RUTHERFOORD, M.D. DURH.,
CAPTAIN, INDIAN MEDICAL SERVICE; CIVIL SURGEON, BILASPUR, CENTRAL PROVINCES, INDIA.

A WELL-NOURISHED and healthy looking man of low caste, aged about 22 years, came to the main dispensary at Bilaspur on Nov. 26th, 1912, complaining of pain on micturition and "dribbling of urine" of five months' duration. On examination there was a small, tender, and hard lump in the middle line of the perineum midway between the anus and scrotum. On passing a sound a calculus could be felt. The urine contained a moderate quantity of pus. The bladder was distended to about 3 inches above the pubis.

An operation was performed on the same day. Chloroform was given, and a sound having been passed and the fact of impaction definitely ascertained, the calculus was cut down on in the middle line. A stone, ovoid in shape and about [illegible] inch in greatest diameter, was removed entire from the posterior portion of the bulbous urethra. A second calculus, which appeared to be about twice the size of the first, was then found lying immediately behind it. As it was large and firmly impacted it was not considered advisable to attempt to remove it entire, and it was accordingly partially crushed with crushing forceps. The more anterior and larger portions were then removed, and it was found that the posterior portion presented an hour-glass-shaped prolongation which extended just within the bladder, the "neck of the hour-glass" being so firmly gripped by the sphincter that this fragment could not be withdrawn. It was accordingly pushed into the bladder, broken with a lithotrite, and the fragments removed with the finger and by washing out. A good deal of oozing of blood from the congested mucous membrane of the posterior portion of the bulbar and from the membranous and prostatic urethra and trigone followed removal, but ceased within an hour from the termination of the operation. The calculi weighed 100 grains and 4 drachms respectively, and appeared to be composed of uric acid and phosphates, the latter preponderating. Convalescence was uneventful, and the patient left the hospital 14 days after operation with a small perineal fistula at the site of the wound.

This case is reported because I imagine that the removal of such large stones from the urethra must be rare. Presumably the smaller calculus was first passed into the urethra and, becoming impacted, increased in size, and its presence led to the subsequent formation of the second stone in the dilated membranous and prostatic urethra. The presence of the prolongation of the second stone through the orifice of the urethra into the bladder is interesting. The case also illustrates the extraordinary power of enduring pain so often exhibited by Indian peasants.

Bilaspur, C.P., India.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SURGICAL SECTION.

After-effects of Gastro-enterostomy.

A meeting of this section was held on Feb. 11th, Mr. **G. H. Makins**, the President, being in the chair.

Dr. **Arthur F. Hertz** read a paper on the Cause and Treatment of Certain Unfavourable After-effects of Gastro-enterostomy. He said that it must have been the experience of almost every surgeon that patients upon whom a gastro-enterostomy had been performed have at some later period complained of symptoms which were often trivial in comparison with those of the condition for which the operation was carried out, but which were none the less sufficient to prevent the patient from regarding the result of the operation as entirely satisfactory. He had gradually come to recognise that the symptoms in a considerable proportion of these cases were due to causes which had not hitherto been described.

1. *Too rapid drainage of the stomach.*—The patient complained of a sensation of fulness, which occurred during each meal and disappeared rapidly; he might find that by eating with extreme slowness he was able to prevent its occurrence. Many patients recognised that it was localised slightly lower than the position where the pain for which the operation was performed had been felt. In some cases the patient also complained of slight diarrhœa, the bowels being opened after each meal. In all patients suffering from this group of symptoms he had found with the X rays that the stomach was small and hypertonic and that the passage of food out of it was extremely rapid, so that a bismuth meal left the stomach in less than an hour and in one case a quarter of an hour after being taken instead of requiring the normal three or four hours. If the patient was watched while he was taking the meal the outflow from the stoma might indeed appear to be almost as rapid as the inflow from the œsophagus. In all cases, whether there was any pyloric obstruction or not at the time of the operation, little or nothing passed through the pylorus, and sometimes the chyme even failed to reach the portion of the pyloric end of the stomach beyond the stoma. The part of the jejunum into which the gastric contents passed from the stoma was consequently distended, and discomfort resulted. In confirmation of this, the situation of the sensation was found to be lower than that due to gastric distension, and corresponded to the upper limit of the situation of the pain felt when the small intestine was subjected to rapid distension. The patient sometimes found that anything which increased the activity of the small intestine, such as exercise or a dose of castor-oil, though it might increase the discomfort, made it disappear more rapidly than it would do otherwise, doubtless because the distension of the jejunum lasted for a shorter period. Confusion with the symptoms arising from a jejunal or gastro-jejunal ulcer was prevented by the fact that the nature of the diet had a considerable influence on the latter, whereas in this type of post-operative indigestion the quantity and not the quality of the food was alone of importance. The diarrhœa was mainly due to the irritation of the bowels by the food, which escaped from the stomach too rapidly for efficient gastric digestion; owing to the absence of the normal stimulation of pancreatic secretion by hydrochloric acid in the duodenum it did not undergo sufficient compensatory digestion in the intestine. It tended to occur after meals owing to the normal gastro-colic reflex, which he had shown* led to an increase in the peristalsis of the colon whenever food entered the stomach. Complete relief or considerable improvement occurred if the patient was instructed to lie down for half an hour or an hour after each meal, as it was found with the X rays that the stomach emptied itself much less rapidly when this posture was assumed, the stoma no longer being in the most dependent position. In some cases it was better to lie on the right or less frequently on the left side, the best position being easily ascertained by watching the rate of evacuation with the X rays. The patient should also be given some active preparation of pancreatic ferments at each meal in order to compensate for the deficiency of the normal secretions. If the sense of fulness was still experienced in spite of the treatment described, small doses of belladonna and of codein should be given half an hour before meals. If all treatment failed to give relief and the patient's symptoms were severe, it might perhaps be necessary to perform an operation with the object of diminishing the size of the stoma; or, if the pylorus was not obstructed, of restoring its activity by completely closing the stoma. The interesting question also arose whether surgeons had not gone somewhat too far in their desire to obtain sufficient drainage, and whether it would not be advisable in the future to make a somewhat smaller stoma than had commonly been made in the last few years.

2. *Situation of the stoma above the upper level of the gastric contents.*—In cases of extreme dilatation of the stomach he had on a number of occasions observed that in the vertical position the whole of the gastric contents accumulated in the lowest part of the stomach in such a way that their upper limit was below the pylorus and might not even reach the lesser curvature. In such cases nothing at all could leave the pylorus, however strong peristalsis was, until the patient lay down. It was clear that in such cases an effective gastro-enterostomy must have the stoma so situated that it remained in the most dependent part of the stomach even when the vertical position was assumed. He had seen one case of dilated stomach due to simple pyloric obstruction, in which no improvement resulted from operation, and in which he found that in the vertical position the upper limit of the gastric contents did not reach as high as the stoma or the pylorus, but that on compressing the lower part of the abdomen the contents rose above the stoma and at once began to pass out of it. By supplying the patient with an abdominal support and making him lie down for an hour after meals on his left side, the position in which he found that the drainage was most rapid, complete relief was eventually obtained. He believed that the notorious absence of success of gastro-enterostomy, when performed for severe atonic dilatation of the stomach without organic obstruction, must be due to a similar cause, drainage through the stoma being mechanically impossible.

Mr. **Edred M. Corner** read a paper on Inferences of Modern Treatment Drawn from Histories of Patients who have Recovered from Perforation of a Gastric or Duodenal Ulcer.

MEDICAL SOCIETY OF LONDON.

Appendicitis: A Plea for Immediate Operation.

A meeting of this society was held on Feb. 10th, Sir **W. Watson Cheyne**, the President, being in the chair.

Mr. **Edmund Owen** opened a discussion by reading a paper entitled Appendicitis: A Plea for Immediate Operation, which was published in The Lancet of Feb. 15th, p. 441.

Mr. **W. H. Battle** said he did not think that anyone with much experience of appendicitis in its acute form could deny that operation, including removal of the appendix, at the commencement of the attack was advisable, and that it constituted the only plan of treatment that could be regarded as certain to yield adequate results in a large series of cases. To advise a patient to submit to operation was the counsel of perfection. Every patient with an attack had to face a serious illness; if it was not fatal it was one which under the best progress was likely to keep him in the house, and probably in his bed, for days. It was liable to recur. It was also a painful illness, which might, being of a septic nature, change its character, and although of mild beginning bring troublesome complications and threaten life for an indefinite period. Should operation be necessitated by any of these complications he might recover but would remain for a long time weak and exhausted. One might also add that the complication which required operation was usually suppuration, when it was not always advisable to do more than incise and drain, and the appendix might require removal later. He had then to face another operation at a later date when apparently well and he thought himself out of

the wood. He had lost very much and gained nothing by his refusal to submit to operation in the first instance Early operation was not only life saving; there were many other advantages, for the period of illness was shortened and, if done quite early, the wound could be closed without drainage, so no weakness remained at the incision for the future development of a hernia Indeed, the after-course might be so mild that the individual could not believe that he had escaped a possibly fatal illness He sometimes accused his medical man of having forced an operation because he wanted to give his friend, the surgeon, "a job"! Mr Battle remembered one instance of this kind in which a gangrenous appendix was removed and an illness which began with a rigor and a temperature of 106° F was promptly checked by operation within 12 hours The appreciation of the parents was shown by the fact that they soon afterwards changed their medical man, because they considered that he had rushed the operation So much harm had been done in the past by the spread of an idea which was prevalent that appendicitis was a harmless, fashionable complaint that even now it was difficult to make people appreciate the fact that it had many forms, and that some of them might be deadly They often knew of some friend who had an attack (perhaps more than one) from which he recovered in a few days, and did not see why they could not be treated as he was, could not understand how they were in any way worse, it was the same disease The conclusion they came to was that if the doctor was right in his diagnosis he did not know as much about the treatment as the one who cured his friend with medicine It must be evident that if early operation, that was, operation within the first 24 hours, were possible in every case the great mortality of the disease, amounting to several hundreds a year in this country and some thousands a year in the United States would be reduced to reasonable dimensions Much had already been done, but the need for urging the operation on the profession most strongly still existed Human nature was however, very obstinate in this country, and if one told a man he *must* have an operation he possibly declined, he was not going to be forced into it The wise man had the operation, but it was not always only the fool who refused If either of them recovered without, after he had been told he must undergo operation, the fact was spread widely amongst his friends, and perhaps the next who developed an attack died, because he thought that he too would score off the doctor It was possible to be too dogmatic. Every general practitioner who had a large practice could tell you of case after case in which recovery ensued, the illness being quite without incident, in some of which at first the initial symptoms were severe—of patients who, applying for removal of the appendix in the "quiet" period, might have had two or more attacks before they came showing typical symptoms with the development of a swelling in the iliac fossa If one told a practitioner of experience that he could not diagnose and give a reliable prognosis in such instances he would naturally smile at the statement, recollecting many in which he had proved his powers It was difficult to believe that any surgeon would try to force an immediate operation in such cases unless he considered there were exceptional circumstances in the patient who was being examined It might be right and expedient, but not imperative As a general statement it was probably true at one time that no one could say what the condition of the appendix was in an acute case until it had been seen, but he ventured to suggest that at the present time we could define with considerable accuracy what was occurring to cause the symptoms in a large number of cases We could not expect every one to do so but he believed that most experienced men could We had learned much in the last ten years The more important thing was to be able to say, even in the early stage "This is an attack in which operation must be performed as soon as possible there are certain symptoms present which show that it would be madness to postpone operation, even for an hour and risk the great dangers to which such an illness exposes this man" Furthermore the influence of a first attack on the production of suppuration around the appendix must be recollected The occurrence of appendicitis in a pregnant woman was so very disastrous that no effort should be spared to get away the appendix at once In children and again after middle life it was very seldom wise to "put it off" When we saw a case shortly after its commencement we should try to come to a conclusion as to the condition of the appendix on which the symptoms depended, and he did not think it less difficult to come to some decision on this point after 24 hours had elapsed But in addition we had to consider the question whether the powers of the patient, unassisted by the surgeon, appeared able to localise the inflammation In some a reply could be given in the negative. it was a fulminating attack, life was already in the balance, and the surgeon must act promptly In others we could not say, and if the patient was in a period of repose, or under the influence of morphia, there might be still more difficulty The sudden cessation of pain was always an important sign of danger Again, we might find proof that the case was settling down, there might be a localised swelling in the iliac fossa or felt per rectum, many surgeons would hesitate to operate under such conditions, even if they thought that there was pus present in the swelling Appendicitis was a septic disease, and localised suppuration ensued in very many cases, not only without causing great disturbance, but without giving the patient uneasiness. It was localised, the septic fluid had been shut in by an area of protective material and the individual was probably saved Further, we knew that even large collections of pus often came away harmlessly by the bowel Toxæmia produced by
absorption from a localised

abdomen, a rapid
pulse rate was associated with a falling temperature), then we could have no hesitation in urging operation And one would find it necessary to drain the peritoneal cavity Regarding operative interference at this stage, there were points which were, he believed, of value Quickness in the manipulation was of importance, but that was not the same thing as hurried handling and disturbance of parts The surgeon should avoid pulling and pushing of the inflamed structures, remove any purulent collection by allowing it to soak in gauze strips, which could be taken away when they had become saturated, search for the appendix after isolating the parts concerned with gauze, if possible wrap the appendix in gauze to prevent contamination of parts as it was taken out, but if it was fixed by old and firm adhesions or so placed that removal would involve repeated or rough handling of inflamed peritoneum, then it had better be left The patient would run less risk than he did from an unduly prolonged operation He could recall more than one case in which he had regretted a removal successfully only after strenuous and prolonged efforts He had thought that it appreciably diminished the patient's chance of recovery If the surgeon did remove the appendix, then he should close the cæcal opening with more than one row of sutures In many cases which were seen later, when the patient was toxæmic with extensive suppuration in the peritoneum, a simple incision and insertion of a large drainage-tube were alone indicated The operation could be done under local anæsthesia, and the effects of drainage were sometimes surprisingly good when combined with proper position in bed and rectal saline infusion One object was to afford the pus an opportunity of escape, so diminishing the quantity of septic fluid from which absorption was taking place, and the tension which was breaking down the protective barriers that had been formed in the attempt of the individual to localise the mischief On the virulence of the septic material which gathered outside the appendix and the power of resistance of the individual, would depend the progress of the case In his opinion boys and young men had far less resisting power than the opposite sex of similar ages, and he thought that much of this was further lessened by the unyielding and more powerful abdominal wall in the former; there was often excessive reflex muscular contraction throughout It was, however, very difficult to say truthfully that because a sloughing appendix, or one which would have perforated before long or one which had perforated already, was found and removed at an operation for acute appendicitis, therefore the patient's life had been saved It was so hard to gauge the power of resistance of an individual It was known he had been saved a very bad illness,

and pneumonia. This attitude was justified by a comparison of the two classes of patients which fell to one's lot to treat—viz., the institutional cases with a relatively high death-rate and the private cases. In the former delay was the rule, and some form of narcotic the curse; in the latter the case was seen much earlier and narcotics were the exception. No one dare deny that a patient having once been a victim to an attack of appendicitis—followed by recovery—in the near future a second attack was inevitable. Short of the full penalty exacted by nature, the lesions left behind after a case had been allowed to drift on on the "wait and see" principle were, to say the least, most unpleasant to face. Amongst the more common were abscess formation, fæcal fistula, considerable damage to the great omentum, permanent adhesions occasionally leading to acute strangulation, subdiaphragmatic abscess, and, lastly, the ever-present ventral hernia. He felt strongly that the bacteriologists had shown us the way to success and had emphasised early interference, and he would be a bold man who turned his head away from the writing on the wall.

Mr. W. H. CLAYTON-GREENE said that the high mortality was due to delay. He agreed as to the value of the early operation in limiting the mortality and preventing complications. His views had been confirmed by the attitude of many physicians who had become more surgical even than the surgeons. It was impossible to say what was going on in the appendix region. Often there was no definite onset. Operation was always necessary, but the type of the operation depended on the condition.

The PRESIDENT said that he operated upon all cases, and considered it the only safe thing to do. He agreed with Mr. George Turner as to the value of a gauze packing with the tube. He always removed the appendix unless the patient was moribund, and did not believe in leaving it temporarily.

Mr. EDMUND OWEN briefly replied.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Specimens.

A PATHOLOGICAL meeting of this society was held on Feb. 7th, Dr. G. P. SHUTER, the President, being in the chair.

The following specimens were exhibited and discussed:—

Dr. ARTHUR R. SAUNDERS: Congenital Hypertrophic Stenosis of the Pylorus, showing, in addition to the usual hypertrophy, a sharp kink at the pyloric end of the stomach almost sufficient in itself to obliterate the lumen of the canal. The infant was admitted to the hospital at the age of 5 weeks for frequent and forcible vomiting. Visible peristalsis could be seen after feeding. The stomach was not dilated, and although it could be distinctly felt through the thin abdominal wall, no mass could be felt in the neighbourhood of the pylorus. As the symptoms improved somewhat under careful feeding, it was hoped that the child would improve sufficiently for a gastro-enterostomy to be performed, but in the ninth week of life an attack of diarrhœa occurred to which it rapidly succumbed.

Mr. ASLETT BALDWIN: 1. Rodent Ulcer of Forearm excised from a man aged 61. The ulcer started in a scar caused by lacerations made by iron nails; it had been present for five years, and sometimes showed signs of healing. A section was also exhibited under the microscope. 2. Tumour of Epididymis from a patient aged 64. The epididymis was about four times the size of the testis, and the central portion had broken down; the testis itself presented no abnormality. Microscopically the tumour did not appear to be tuberculous or syphilitic, but merely inflammatory; various opinions, however, were given as to its nature. The patient had had hydrocele for years, and a month before admission to hospital was suddenly seized with severe pain and inflammation in the left side of the scrotum. No urethritis or injury. 3. Hypernephroma of Left Kidney from a woman of 60. No urinary or other symptoms except some dragging pain in left side of abdomen. Removal about a year ago, and patient still well.

Mr. W. MCADAM ECCLES: 1. Mucocele of Gall-bladder removed post mortem. Calculus impacted in cystic duct. 2. Mucocele of Gall-bladder removed from a lady who had for many years symptoms of dyspepsia, but never jaundice. The cystic duct was tied, and she made a very good recovery. 3. Tuberculous Salpingitis. This specimen was removed from a woman aged 25; she made a perfect recovery, is now married, but has not been pregnant. There were tubercles over the parietal peritoneum of Douglas's pouch. In reply to some remarks, Mr. McAdam Eccles said that in serous tuberculous peritonitis laparotomy was generally followed by a cure. He believed that peritonitis of a tuberculous nature in the female was caused by infection from the Fallopian tubes, and it was best to remove the tubes whenever possible. In his experience this type of case hardly ever did well if the tubes were left. 4. Five Calculi from the Bladder of a woman aged 29. Since the age of 17 up to date of operation she had passed no less than 278 calculi. The stones exhibited were passed spontaneously with great pain, and showed the wonderful dilatability of the female urethra. She did not have any incontinence of urine. 5. Malignant Teratoma of the Testis removed from a man aged 32. It was a mixed tumour containing elements showing its teratomatous nature, and it had also sarcomatous elements. The patient died six months after operation with secondary deposits.

Dr. HAROLD PRITCHARD: Specimens from a case of Banti's Disease, a late and terminal stage of splenic anæmia. The patient died at the age of 9 years with all the signs of portal obstruction and marked ascites. The liver was small and contracted, with an irregular surface, and microscopically showed the changes typically found in multilobular cirrhosis. The spleen was large and tough and contained some considerable amount of fibrous tissue. The peritoneum was thickened.

Mr. T. JEFFERSON FAULDER: Guillotined Tonsils shown to illustrate that practically any kind of tonsil can be removed complete in its capsule simply with a guillotine and a short anæsthetic. The series presented included all varieties of tonsils—the common bi-lobed type, the flat tonsil, all grades of embedded tonsil, and tonsils reduced to the condition of mere pyogenic membranes. Many of them had been operated on previously. In reply to questions by Mr. MCADAM ECCLES, Mr. RICKARD W. LLOYD, and the PRESIDENT, the details of the operation were explained, and Mr. FAULDER pointed out that the operation called enucleation was invented to meet the cases in which the guillotine, as used originally, had failed to cure, and the necessity for the invention of enucleation sufficiently showed that the clinical results obtained by slicing off a portion of the tonsil were often unsatisfactory. By the new method, introduced by Sluder, one could remove as much or as little of the tonsil as was thought desirable, and the operation was a much less formidable procedure than enucleation by the methods hitherto adopted.

Dr. H. H. SANGUINETTI: Acid-fast Organisms from Distilled Water closely resembling tubercle bacilli. It was important to bear in mind this possible source of contamination when investigating the presence of tubercle bacilli, especially by the antiformin method or by the inoscopic method of Jousset.

Dr. SANGUINETTI also exhibited for Dr. J. M. BERNSTEIN and Dr. R. R. ELWORTHY the following specimens from the Pathological Department of the West London Hospital: 1. Splenomedullary Leucocythæmia showing large basophile myelocytes stained by Wright's method. 2. Spirochæta Pallida from primary sore on lip. 3. Carcinoma of Appendix.—(Mr. MCADAM ECCLES remarked on the interest of these cases, occurring so often in quite young subjects. This specimen was from a girl aged 13; symptoms of chronic appendicitis were present, and when he removed the organ, a short stumpy appendix, it showed microscopically a typical carcinoma. These cases generally recovered, and did not have any recurrence in glands or viscera).—4. Tuberculous Pneumonia. 5. Intussusception of Ileum into Cæcum discovered post mortem in a boy aged 1 year and 10 months. There was no peritonitis. The child was brought to hospital without any definite history of abdominal symptoms, and while being examined died. He was well developed and in other respects healthy, and the abdomen when examined was flaccid. 6. Interstitial Nephritis. 7. Melanotic Sarcoma of Spleen and Liver. 8. Shirt Stud obstructing Larynx.
